

# Dual 12-/14-/16-Bit *nano*DAC® with 5 ppm/°C On-Chip Reference

# AD5623R/AD5643R/AD5663R

#### **FEATURES**

Low power, smallest pin-compatible, dual nanoDAC

AD5663R: 16 bits AD5643R: 14 bits AD5623R: 12 bits

User-selectable external or internal reference

**External reference default** 

On-chip 1.25 V/2.5 V, 5 ppm/°C reference 10-lead MSOP and 3 mm × 3 mm LFCSP\_WD

2.7 V to 5.5 V power supply

Guaranteed monotonic by design

Power-on reset to zero scale

Per channel power-down

Serial interface; up to 50 MHz

Hardware LDAC and CLR functions

#### **APPLICATIONS**

Process control
Data acquisition systems
Portable battery-powered instruments
Digital gain and offset adjustment
Programmable voltage and current sources
Programmable attenuators

#### **GENERAL DESCRIPTION**

The AD5623R/AD5643R/AD5663R, members of the nanoDAC family, are low power, dual 12-, 14-, and16-bit buffered voltageout DACs that operate from a single 2.7 V to 5.5 V supply and are guaranteed monotonic by design.

The AD5623R/AD5643R/AD5663R have an on-chip reference. The AD5623R-3/AD5643R-3/AD5663R-3 have a 1.25 V, 5 ppm/°C reference, giving a full-scale output of 2.5 V; and the AD5623R-5/AD5643R-5/AD5663R-5 have a 2.5 V, 5 ppm/°C reference, giving a full-scale output of 5 V. The on-chip reference is off at power-up, allowing the use of an external reference; and all devices can be operated from a single 2.7 V to 5.5 V supply. The internal reference is turned on by writing to the DAC.

The parts incorporate a power-on reset circuit that ensures that the DAC output powers up to 0 V and remains there until a valid write takes place. The part contains a power-down feature that reduces the current consumption of the device to 480 nA at 5 V and provides software-selectable output loads while in power-down mode.

#### FUNCTIONAL BLOCK DIAGRAM

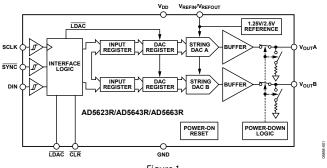

Figure 1.

Table 1. Related Devices

Part No.	Description
AD5663	2.7 V to 5.5 V, dual16-bit DAC, external reference

The low power consumption of this part in normal operation makes it ideally suited to portable, battery-operated equipment.

The AD5623R/AD5643R/AD5663R use a versatile, 3-wire serial interface that operates at clock rates up to 50 MHz, and they are compatible with standard SPI\*, QSPI™, MICROWIRE™, and DSP interface standards. The on-chip precision output amplifier enables rail-to-rail output swing to be achieved.

#### **PRODUCT HIGHLIGHTS**

- 1. Dual 12-, 14-, and 16-bit DAC.
- 2. On-chip 1.25 V/2.5 V, 5 ppm/°C reference.
- 3. Available in 10-lead MSOP and 10-lead, 3 mm  $\times$  3 mm LFCSP\_VQ.
- 4. Low power. Typically consumes 0.6 mW at 3 V and 1.25 mW at 5 V.
- 5. 4.5 μs maximum settling time for the AD5623R.

<sup>&</sup>lt;sup>3</sup> Guaranteed by design and characterization, not production tested.

<sup>&</sup>lt;sup>4</sup> Interface inactive. All DACs active. DAC outputs unloaded. <sup>5</sup> Both DACs powered down.

#### **TIMING CHARACTERISTICS**

All input signals are specified with  $t_R = t_F = 1$  ns/V (10% to 90% of  $V_{\rm DD}$ ) and timed from a voltage level of ( $V_{\rm IL} + V_{\rm IH}$ )/2.  $V_{\rm DD} = 2.7$  V to 5.5 V; all specifications  $T_{\rm MIN}$  to  $T_{\rm MAX}$ , unless otherwise noted.

Table 5.

	Limit at T <sub>MIN</sub> , T <sub>MAX</sub>		
Parameter	$V_{DD} = 2.7 \text{ V to } 5.5 \text{ V}$	Unit	Conditions/Comments

<sup>&</sup>lt;sup>2</sup> Maximum SCLK frequency is 50 MHz at  $V_{DD} = 2.7 \text{ V}$  to 5.5 V.

### **ABSOLUTE MAXIMUM RATINGS**

 $T_A = 25$ °C, unless otherwise noted.

#### Table 6.

Table 0.	
Parameter	Rating
V <sub>DD</sub> to GND	-0.3 V to 7 V
V <sub>OUT</sub> to GND	$-0.3 \text{ V to V}_{DD} + 0.3 \text{ V}$
V <sub>REFIN</sub> /V <sub>REFOUT</sub> to GND	$-0.3 \text{ V to V}_{DD} + 0.3 \text{ V}$
Digital Input Voltage to GND	$-0.3 \text{ V to V}_{DD} + 0.3 \text{ V}$
Operating Temperature Range	
Industrial	−40°C to +105°C
Storage Temperature Range	−65°C to +150°C
Junction Temperature (T <sub>J</sub> max)	150°C
Power Dissipation	$(T_J \max - T_A)/\theta_{JA}$
LFCSP Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	61°C/W
MSOP Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	142°C/W
$\theta_{JC}$ Thermal Impedance	43.7°C/W
Reflow Soldering Peak Temperature	
Pb-Free	260(+0/-5)°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

#### **ESD CAUTION**

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

# PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

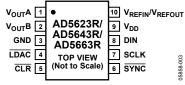

Figure 3. Pin Configuration

**Table 7. Pin Function Descriptions** 

Pin No.	Mnemonic	Description
1	V <sub>OUT</sub> A	Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
2	V <sub>оит</sub> В	Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
3	GND	Ground Reference Point for All Circuitry on the Part.
4	LDAC	Pulsing this pin low allows any or all DAC registers to be updated if the input registers have new data. This allows simultaneous update of all DAC outputs. Alternatively, this pin can be tied permanently low.
5	CLR	Asynchronous Clear Input. The CLR input is falling edge sensitive. While CLR is low, all LDAC pulses are ignored. When CLR is activated, zero scale is loaded to all input and DAC registers. This clears the output to 0 V. The part exits clear code mode on the 24th falling edge of the next write to the part. If CLR is activated during a write sequence, the write is aborted.
6	SYNC	Level-Triggered Control Input (Active Low). This is the frame synchronization signal for the input data.  When SYNC goes low, it enables the input shift register, and data is transferred in on the falling edges of the following clocks. The DAC is updated following the 24th clock cycle unless SYNC is taken high before this edge, in which case the rising edge of SYNC acts as an interrupt and the write sequence is ignored by the DAC.
7	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input.  Data can be transferred at rates up to 50 MHz.
8	DIN	Serial Data Input. This device has a 24-bit shift register. Data is clocked into the register on the falling edge of the serial clock input.
9	V <sub>DD</sub>	Power Supply Input. These parts can be operated from 2.7 V to 5.5 V, and the supply should be decoupled with a 10 $\mu$ F capacitor in parallel with a 0.1 $\mu$ F capacitor to GND.
10	V <sub>REFIN</sub> /V <sub>REFOUT</sub>	Common Reference Input/Reference Output Pin. When the internal reference is selected, this is the reference output pin. When using an external reference, this is the reference input pin. The default for this pin is a reference input.

### **TERMINOLOGY**

#### Relative Accuracy or Integral Nonlinearity (INL)

For the DAC, relative accuracy or integral nonlinearity is a measurement of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function. A typical INL vs. code plot is shown in Figure 5.

#### Differential Nonlinearity (DNL)

Differential nonlinearity (DNL) is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of  $\pm 1$  LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. A typical DNL vs. code plot is shown in Figure 9.

#### **Zero-Scale Error**

Zero-scale error is the measurement of the output error when zero code (0x0000) is loaded to the DAC register. Ideally, the output should be 0 V. The zero-scale error is always positive in the AD566x3R because the output of the DAC cannot go below 0 V. It is due to a combination of the offset errors in the DAC and the output amplifier. Zero-scale error is expressed in mV. A plot of zero-scale error vs. temperature is shown in Figure 26.

#### **Full-Scale Error**

Full-scale error is the measurement of the output error when full-scale code (0xFFFF) is loaded into the DAC register. Ideally, the output should be  $V_{\rm DD}-1$  LSB. Full-scale error is expressed in percent of full-scale range. A plot of full-scale error vs. temperature is shown in Figure 25.

#### **Gain Error**

Gain error is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from ideal, expressed as a percent of the full-scale range.

#### Zero-Scale Error Drift

Zero-scale error drift is the measurement of the change in zero-scale error with a change in temperature. It is expressed in  $\mu V/^{\circ}C$ .

#### **Gain Temperature Coefficient**

Gain temperature coefficient is a measurement of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range)/°C.

#### Offset Error

Offset error is a measure of the difference between  $V_{\text{OUT}}$  (actual) and  $V_{\text{OUT}}$  (ideal) expressed in mV in the linear region of the transfer function. Offset error is measured on the AD56x3R with code 512 loaded in the DAC register. It can be negative or positive.

#### DC Power Supply Rejection Ratio (PSRR)

PSRR indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in  $V_{\rm OUT}$  to a change in  $V_{\rm DD}$  for full-scale output of the DAC. It is measured in dB.  $V_{\rm REF}$  is held at 2 V, and  $V_{\rm DD}$  is varied by  $\pm 10\%$ .

#### **Output Voltage Settling Time**

Output voltage settling time is the amount of time it takes for the output of a DAC to settle to a specified level for a 1/4 to 3/4 full-scale input change and is measured from the 24th falling edge of SCLK.

#### Digital-to-Analog Glitch Impulse

The impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-s and is measured when the digital input code is changed by 1 LSB at the major carry transition (0x7FFF to 0x8000). See Figure 38.

#### Digital Feedthrough

A measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC, digital feedthrough is measured when the DAC output is not updated. It is specified in nV-s, and it is measured with a full-scale code change on the data bus, that is, from all 0s to all 1s and vice versa.

#### Reference Feedthrough

Reference feedthrough is the ratio of the amplitude of the signal at the DAC output to the reference input when the DAC output is not being updated (that is,  $\overline{\text{LDAC}}$  is high). It is expressed in dB.

#### **Noise Spectral Density**

Noise spectral density is a measurement of the internally generated random noise. Random noise is characterized as a spectral density  $(nV/\sqrt{Hz})$ . It is measured by loading the DAC to midscale and measuring noise at the output. A plot of noise spectral density is shown in **Figure 44**.

#### DC Crosstalk

DC crosstalk is the dc change in the output level of one DAC in response to a change in the output of another DAC. It is measured with a full-scale output change on one DAC (or soft power-down and power-up) while monitoring another DAC kept at midscale. It is expressed in  $\mu V$ .

DC crosstalk due to load current change is a measure of the impact that a change in load current on one DAC has to another DAC kept at midscale. It is expressed in  $\mu V/mA$ .

#### **Digital Crosstalk**

Digital crosstalk is the glitch impulse transferred to the output of one DAC at midscale in response to a full-scale code change (all 0s to all 1s and vice versa) in the input register of another DAC. It is measured in standalone mode and is expressed in nV-s.

#### **Analog Crosstalk**

Analog crosstalk is the glitch impulse transferred to the output of one DAC due to a change in the output of another DAC. It is measured by loading one of the input registers with a full-scale code change (all 0s to all 1s and vice versa) while keeping LDAC high. Then pulse  $\overline{\text{LDAC}}$  low and monitor the output of the DAC whose digital code was not changed. The area of the glitch is expressed in nV-s.

#### **DAC-to-DAC Crosstalk**

DAC-to-DAC crosstalk is the glitch impulse transferred to the output of one DAC due to a digital code change and subsequent output change of another DAC. This includes both digital and analog crosstalk. It is measured by loading one of the DACs with a full-scale code change (all 0s to all 1s and vice versa) with  $\overline{\text{LDAC}}$  low and monitoring the output of another DAC. The energy of the glitch is expressed in nV-s.

#### **Multiplying Bandwidth**

The amplifiers within the DAC have a finite bandwidth. The multiplying bandwidth is a measure of this. A sine wave on the reference (with full-scale code loaded to the DAC) appears on the output. The multiplying bandwidth is the frequency at which the output amplitude falls to 3 dB below the input.

#### **Total Harmonic Distortion (THD)**

Total harmonic distortion is the difference between an ideal sine wave and its attenuated version using the DAC. The sine wave is used as the reference for the DAC, and the THD is a measurement of the harmonics present on the DAC output. It is measured in dB.

### THEORY OF OPERATION

#### D/A SECTION

The AD5623R/AD5643R/AD5663R DAC is fabricated on a CMOS process. The architecture consists of a string DAC followed by an output buffer amplifier. Figure 49 shows a block diagram of the DAC architecture.

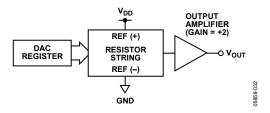

Figure 49. DAC Architecture

Because the input coding to the DAC is straight binary, the ideal output voltage when using an external reference is given by

$$V_{OUT} = V_{REFIN} \times \left(\frac{D}{2^N}\right)$$

The ideal output voltage when using the internal reference is given by

$$V_{OUT} = 2 \times V_{REFOUT} \times \left(\frac{D}{2^N}\right)$$

where:

*D* is the decimal equivalent of the binary code that is loaded to the DAC register:

0 to 4095 for AD5623R (12 bit) 0 to 16,383 for AD5643R (14 bit) 0 to 65,535 for AD5663R (16 bit)

*N* is the DAC resolution.

#### **RESISTOR STRING**

The resistor string section is shown in Figure 50. It is simply a string of resistors, each of Value R. The code loaded to the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic.

#### **OUTPUT AMPLIFIER**

The output buffer amplifier can generate rail-to-rail voltages on its output, which gives an output range of 0 V to  $V_{\rm DD}.$  It can drive a load of 2  $k\Omega$  in parallel with 1000 pF to GND. The source and sink capabilities of the output amplifier can be seen in Figure 31. The slew rate is 1.8 V/µs with a 1/4 to 3/4 full-scale settling time of 10 µs.

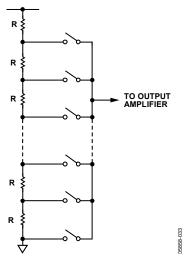

Figure 50. Resistor String

#### **INTERNAL REFERENCE**

The AD5623R/AD5643R/AD5663R on-chip reference is off at power-up and is enabled via a write to a control register. See the Internal Reference Setup section for details.

The AD56x3R-3 has a 1.25 V, 5 ppm/°C reference, giving a full-scale output of 2.5 V. The AD56x3R-5 has a 2.5 V, 5 ppm/°C reference, giving a full-scale output of 5 V. The internal reference associated with each part is available at the V<sub>REFOUT</sub> pin. A buffer is required if the reference output is used to drive external loads. When using the internal reference, it is recommended that a 100 nF capacitor be placed between reference output and GND for reference stability.

#### **EXTERNAL REFERENCE**

The  $V_{REFIN}$  pin on the AD56x3R-3 and the AD56x3R-5 allows the use of an external reference if the application requires it. The on-chip reference is off at power-up, and this is the default condition. The AD56x3R-3 and the AD56x3R-5 can be operated from a single 2.7 V to 5.5 V supply.

#### **SERIAL INTERFACE**

The AD5623R/AD5643R/AD5663R have a 3-wire serial interface (SYNC, SCLK, and DIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards, as well as with most DSPs. See Figure 2 for a timing diagram of a typical write sequence.

The write sequence begins by bringing the SYNC line low. Data from the DIN line is clocked into the 24-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high as 50 MHz, making the AD5623R/AD5643R/AD5663R compatible with high speed DSPs. On the 24th falling clock edge, the last data bit is clocked in and the programmed function is executed, for example, a change in DAC register contents and/or a change in the mode of operation.

At this stage, the  $\overline{\text{SYNC}}$  line can be kept low or be brought high. In either case, it must be brought high for a minimum of 15 ns before the next write sequence, so that a falling edge of  $\overline{\text{SYNC}}$  can initiate the next write sequence.

Because the  $\overline{SYNC}$  buffer draws more current when  $V_{\rm IN}=2~V$  than it does when  $V_{\rm IN}=0.8~V, \overline{SYNC}$  should be idled low between write sequences for even lower power operation. As mentioned previously, it must, however, be brought high again just before the next write sequence.

#### **INPUT SHIFT REGISTER**

The input shift register is 24 bits wide (see Figure 52). The first two bits are don't cares. The next three are Command Bit C2 to Command Bit C0 (see Table 8), followed by the 3-bit DAC Address A2 to DAC Address A0 (see Table 9), and, finally, the 16-, 14-, and 12-bit data-word.

The data-word comprises the 16-, 14-, and 12-bit input codes, followed by zero, two, or four don't care bits, for the AD5663R, AD5643R, and AD5623R, respectively (see Figure 51, Figure 52, and Figure 53). The data bits are transferred to the DAC register on the 24th falling edge of SCLK.

**Table 8. Command Definition** 

C2	C1	C0	Command
0	0	0	Write to Input Register n
0	0	1	Update DAC Register n
0	1	0	Write to Input Register <i>n</i> , update all (software LDAC)
0	1	1	Write to and update DAC Channel n
1	0	0	Power down DAC (power up)
1	0	1	Reset
1	1	0	LDAC register setup
1	1	1	Internal reference setup (on/off)

Table 9. Address Command

A2	A1	A0	ADDRESS (n)
0	0	0	DAC A
0	0	1	DAC B
0	1	0	Reserved
0	1	1	Reserved
1	1	1	All DACs

#### **SYNC INTERRUPT**

In a normal write sequence, the SYNC line is kept low for at least 24 falling edges of SCLK, and the DAC is updated on the 24th falling edge. However, if SYNC is brought high before the 24th falling edge, this acts as an interrupt to the write sequence. The shift register is reset, and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs (see Figure 54).

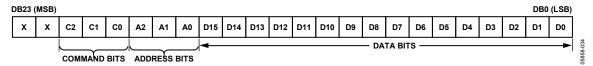

Figure 51. AD5663R Input Shift Register Contents

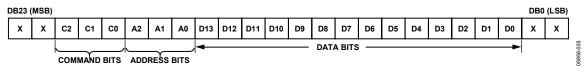

Figure 52. AD5643R Input Shift Register Contents

Figure 53. AD5623R Input Shift Register Contents

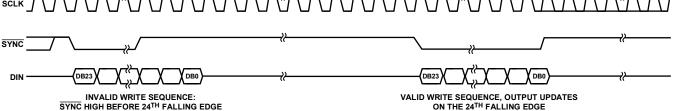

Figure 54. SYNC Interrupt Facility

#### **POWER-ON RESET**

The AD5623R/AD5643R/AD5663R contain a power-on reset circuit that controls the output voltage during power-up. The AD5623R/AD5643R/AD5663R DACs output power up to 0 V, and the output remains there until a valid write sequence is made to the DACs. This is useful in applications where it is important to know the state of the output of the DACs while they are in the process of powering up. Any events on  $\overline{\text{LDAC}}$  or  $\overline{\text{CLR}}$  during power-on reset are ignored.

#### **SOFTWARE RESET**

The AD5623R/AD5643R/AD5663R contain a software reset function. Command 101 is reserved for the software reset function (see Table 8). The software reset command contains two reset modes that are software-programmable by setting bit DB0 in the control register. Table 10 shows how the state of the bit corresponds to the mode of operation of the device.

Table 12 shows the contents of the input shift register during the software reset mode of operation.

Table 10. Software Reset Modes for the AD5623R/AD5643R/AD5663R

Software Reset Mode	Software Reset Mode				
DB0	Registers Reset to Zero				
0	DAC register				
	Input register				
1 (Power-on Reset)	DAC register				
	Input register				
	LDAC register				
	Power-down register				
	Internal reference setup register				

#### **POWER-DOWN MODES**

The AD5623R/AD5643R/AD5663R contain four separate modes of operation. Command 100 is reserved for the power-down function (see Table 8). These modes are software-programmable by setting Bit DB5 and Bit DB4 in the control register. Table 11 shows how the state of the bits corresponds to the mode of operation of the device. Any or all DACs (DAC B and DAC A) can be powered down to the selected mode by setting the corresponding two bits (Bit DB1 and Bit DB0) to 1.

By executing the same Command 100, any combination of DACs can be powered up by setting Bit DB5 and Bit DB4 to normal operation mode. Again, to select which combination of DAC channels to power up, set the corresponding bits (Bit DB1 and Bit DB0) to 1. See Table 13 for contents of the input shift register during power-down/power-up operation.

The DAC output powers up to the value in the input register while LDAC is low. If LDAC is high, the DAC ouput powers up to the value held in the DAC register before power-down.

Table 11. Modes of Operation for the AD5623R/AD5643R/AD5663R

DB5	DB4	Operating Mode
0	0	Normal operation
		Power-down modes
0	1	1 kΩ to GND
1	0	100 kΩ to GND
1	1	Three-state

When both Bit DB1 and Bit DB2 are set to 0, the part works normally, with its normal power consumption of 250  $\mu A$  at 5 V. However, for the three power-down modes, the supply current falls to 480 nA at 5 V (200 nA at 3 V). Not only does the supply current fall, but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode. The outputs can either be connected internally to GND through a 1  $k\Omega$  or 100  $k\Omega$  resistor or left open-circuited (three-state) (see Figure 55).

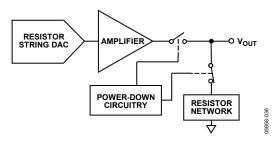

Figure 55. Output Stage During Power-Down

The bias generator, the output amplifier, the resistor string, and other associated linear circuitry are shut down when power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 4  $\mu s$  for both  $V_{\rm DD}=5~V$  and  $V_{\rm DD}=3~V$  (see Figure 37).

#### **LDAC FUNCTION**

The AD5623R/AD5643R/AD5663R DACs have double-buffered interfaces consisting of two banks of registers: input registers and DAC registers. The input registers are connected directly to the input shift register, and the digital code is transferred to the relevant input register on completion of a valid write sequence. The DAC registers contain the digital code used by the resistor strings.

Access to the DAC registers is controlled by the  $\overline{\text{LDAC}}$  pin. When the  $\overline{\text{LDAC}}$  pin is high, the DAC registers are latched and the input registers can change state without affecting the contents of the DAC registers. When  $\overline{\text{LDAC}}$  is brought low, however, the DAC registers become transparent and the contents of the input registers are transferred to them. The double-buffered interface is useful if the user requires simultaneous updating of all DAC outputs. The user can write to one of the input registers individually and then, by bringing  $\overline{\text{LDAC}}$  low when writing to the other DAC input register, all outputs will update simultaneously.

These parts each contain an extra feature whereby a DAC register is not updated unless its input register has been updated since the last time  $\overline{\text{LDAC}}$  was brought low. Normally, when  $\overline{\text{LDAC}}$  is brought low, the DAC registers are filled with the contents of the input registers. In the case of the AD5623R/AD5643R/AD5663R, the DAC register updates only if the input register has changed since the last time the DAC register was updated, thereby removing unnecessary digital crosstalk.

The outputs of all DACs can be simultaneously updated, using the hardware LDAC pin.

Synchronous LDAC: The DAC registers are updated after new data is read in on the falling edge of the 24th SCLK pulse.

LDAC can be permanently low or pulsed as shown in Figure 2.

Asynchronous  $\overline{\text{LDAC}}$ : The outputs are not updated at the same time that the input registers are written to. When  $\overline{\text{LDAC}}$  goes low, the DAC registers are updated with the contents of the input register.

The  $\overline{\text{LDAC}}$  register gives the user full flexibility and control over the hardware  $\overline{\text{LDAC}}$  pin. This register allows the user to select which combination of channels to simultaneously update when the hardware  $\overline{\text{LDAC}}$  pin is executed. Setting the  $\overline{\text{LDAC}}$  bit register to 0 for a DAC channel means that the update of this channel is controlled by the  $\overline{\text{LDAC}}$  pin. If this bit is set to 1, this channel synchronously updates; that is, the DAC register is updated after new data is read in, regardless of the state of the  $\overline{\text{LDAC}}$  pin. It effectively sees the  $\overline{\text{LDAC}}$  pin as being pulled low. See Table 15 for the  $\overline{\text{LDAC}}$  register mode of operation. This flexibility is useful in applications where the user wants to simultaneously update select channels while the rest of the channels are synchronously updating.

Writing to the DAC using Command 110 loads the 2-bit  $\overline{LDAC}$  register [DB1:DB0]. The default for each channel is 0; that is, the  $\overline{LDAC}$  pin works normally. Setting the bits to 1 means the DAC register is updated, regardless of the state of the  $\overline{LDAC}$  pin. See Table 14 for contents of the input shift register during the  $\overline{LDAC}$  register setup command.

Table 15. LDAC Register Mode of Operation

Load DAC Register

0	1/0	Determined by LDAC pin						
1	x = don't care	The DAC registers are updated after new data is read in on the falling edge of the 24th SCLK pulse.						

#### **INTERNAL REFERENCE SETUP**

The on-chip reference is off at power-up by default. This reference can be turned on or off by setting a software programmable bit, DB0 in the control register. Table 16 shows how the state of the bit corresponds to the mode of operation. Command 111 is reserved for setting up the internal reference (see Table 8). See Table 17 for the contents of the input shift register during the internal reference set-up command.

#### **MICROPROCESSOR INTERFACING**

# AD5623R/AD5643R/AD5663R to Blackfin® ADSP-BF53X Interface

Figure 56 shows a serial interface between the AD5623R/AD5643R/AD5663R and the Blackfin ADSP-BF53X microprocessor. The ADSP-BF53X processor family incorporates two dual-channel synchronous serial ports, SPORT1 and SPORT0, for serial and multiprocessor communications. Using SPORT0 to connect to the AD5623R/AD5643/AD5663R, the setup for the interface is as follows: DT0PRI drives the DIN pin of the AD5623R/AD5643/AD5663R, while TSCLK0 drives the SCLK of the parts. The SYNC is driven from TFS0.

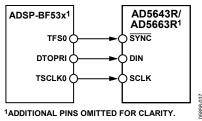

Figure 56. AD5623R/AD5643R/AD5663R to Blackfin ADSP-BF53X Interface

#### AD5623R/AD5643R/AD5663R to 68HC11/68L11 Interface

Figure 57 shows a serial interface between the AD5623R/AD5643R/AD5663R and the 68HC11/68L11 microcontroller. SCK of the 68HC11/68L11 drives the SCLK of the AD5623R/AD5643R/AD5663R, and the MOSI output drives the serial data line of the DAC.

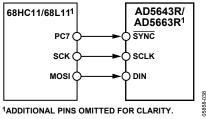

Figure 57. AD5623R/AD5643R/AD5663R to 68HC11/68L11 Interface

The SYNC signal is derived from a port line (PC7). The setup conditions for correct operation of this interface are as follows: The 68HC11/68L11 is configured with its CPOL bit as 0, and its CPHA bit as 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured as described previously, data appearing on the MOSI output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle.

Data is transmitted MSB first. To load data to the AD5623R/AD5643R/AD5663R, PC7 is left low after the first eight bits are transferred, and a second serial write operation is performed to the DAC. PC7 is taken high at the end of this procedure.

#### AD5623R/AD5643R/AD5663R to 80C51/80L51 Interface

Figure 58 shows a serial interface between the AD5623R/AD5643R/AD5663R and the 80C51/80L51 microcontroller. The setup for the interface is as follows: TxD of the 80C51/80L51 drives SCLK of the AD5623R/AD5643R/AD5663R, and RxD drives the serial data line of the part. The \$\overline{\text{SYNC}}\$ signal is again derived from a bit-programmable pin on the port. In this case, Port Line P3.3 is used. When data is to be transmitted to the AD5643/AD5663R, P3.3 is taken low. The 80C51/80L51 transmit data in 8-bit bytes only; thus, only eight falling clock edges occur in the transmit cycle. To load data to the DAC, P3.3 is left low after the first eight bits are transmitted, and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken high following the completion of this cycle.

The 80C51/80L51 output the serial data in a format that has the LSB first. The AD5623R/AD5643R/AD5663R must receive data with the MSB first. The 80C51/80L51 transmit routine should take this into account.

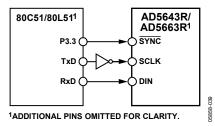

Figure 58. AD5623R/AD5643R/AD5663R to 80C512/80L51 Interface

#### AD5623R/AD5643R/AD5663R to MICROWIRE Interface

Figure 59 shows an interface between the AD5623R/AD5643R/ AD5663R and any MICROWIRE-compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the AD5623R/AD5643R/AD5663R on the rising edge of the SK.

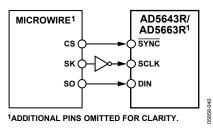

Figure 59. AD5623R/AD5643R/AD5663R to MICROWIRE Interface

### **APPLICATIONS**

# USING A REFERENCE AS A POWER SUPPLY FOR THE AD5623R/AD5643R/AD5663R

Because the supply current required by the AD5623R/AD5643R/AD5663R is extremely low, an alternative option is to use a voltage reference to supply the required voltage to the parts (see Figure 60). This is especially useful if the power supply is quite noisy or if the system supply voltages are at some value other than 5 V or 3 V, for example, 15 V. The voltage reference outputs a steady supply voltage for the AD5623R/AD5643R/AD5663R. If the low dropout REF195 is used, it must supply 500  $\mu A$  of current to the AD5623R/AD5643R/AD5663R, with no load on the output of the DAC. When the DAC output is loaded, the REF195 also needs to supply the current to the load. The total current required (with a 5 k $\Omega$  load on the DAC output) is

$$500 \,\mu\text{A} + (5 \,\text{V}/5 \,\text{k}\Omega) = 1.25 \,\text{mA}$$

The load regulation of the REF195 is typically 2 ppm/mA, which results in a 3 ppm (15  $\mu$ V) error for the 1.5 mA current drawn from it. This corresponds to a 0.196 LSB error.

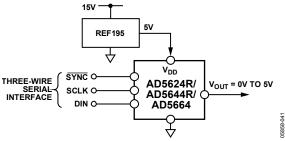

Figure 60. REF195 as Power Supply to the AD5623R/AD5643R/AD5663R

#### **BIPOLAR OPERATION USING THE AD5663R**

The AD5663R has been designed for single-supply operation, but a bipolar output range is also possible using the circuit in Figure 61. The circuit gives an output voltage range of  $\pm 5$  V. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

The output voltage for any input code can be calculated as follows:

$$V_{O} = \left[V_{DD} \times \left(\frac{D}{65,536}\right) \times \left(\frac{R1 + R2}{R1}\right) - V_{DD} \times \left(\frac{R2}{R1}\right)\right]$$

where *D* represents the input code in decimal (0 to 65,535). With  $V_{DD} = 5$  V, RI = R2 = 10 k $\Omega$ ,

$$V_{\rm O} = \left(\frac{10 \times D}{65,536}\right) - 5 \text{ V}$$

This is an output voltage range of  $\pm 5$  V, with 0x0000 corresponding to a -5 V output, and 0xFFFF corresponding to a +5 V output.

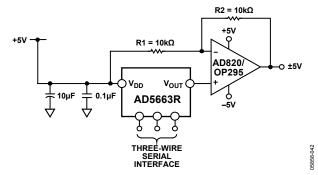

Figure 61. Bipolar Operation with the AD5663R

# USING THE AD5663R WITH A GALVANICALLY ISOLATED INTERFACE

In process control applications in industrial environments, it is often necessary to use a galvanically isolated interface to protect and isolate the controlling circuitry from any hazardous common-mode voltages that can occur in the area where the DAC is functioning. *i*Coupler® provides isolation in excess of 2.5 kV. The AD5663R uses a 3-wire serial logic interface, so the ADuM1300 three-channel digital isolator provides the required isolation (see Figure 62). The power supply to the part also needs to be isolated, which is done by using a transformer. On the DAC side of the transformer, a 5 V regulator provides the 5 V supply required for the AD5663R.

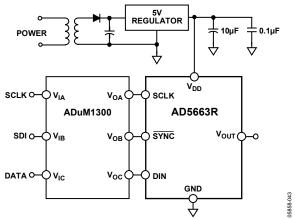

Figure 62. AD5663R with a Galvanically Isolated Interface

#### POWER SUPPLY BYPASSING AND GROUNDING

When accuracy is important in a circuit, it is helpful to carefully consider the power supply and ground return layout on the board. The printed circuit board containing the AD5663R should have separate analog and digital sections, each having its own area of the board.

If the AD5663R is in a system where other devices require an AGND-to-DGND connection, the connection should be made at one point only. This ground point should be as close as possible to the AD5663R.

The power supply to the AD5663R should be bypassed with  $10~\mu F$  and  $0.1~\mu F$  capacitors. The capacitors should be located as close as possible to the device, with the  $0.1~\mu F$  capacitor ideally right up against the device. The  $10~\mu F$  capacitors are the tantalum bead type. It is important that the  $0.1~\mu F$  capacitor have low effective series resistance (ESR) and effective series inductance (ESI), for example, common ceramic types of capacitors.

This 0.1  $\mu F$  capacitor provides a low impedance path to ground for high frequencies caused by transient currents due to internal logic switching.

The power supply line itself should have as large a trace as possible to provide a low impedance path and to reduce glitch effects on the supply line. Clocks and other fast switching digital signals should be shielded from other parts of the board by digital ground. Avoid crossover of digital and analog signals, if possible. When traces cross on opposite sides of the board, ensure that they run at right angles to each other to reduce feedthrough effects through the board. The best board layout technique is the microstrip technique, where the component side of the board is dedicated to the ground plane only and the signal traces are placed on the solder side. However, this is not always possible with a 2-layer board.

#### **ORDERING GUIDE**

Model	Temperature Range	Accuracy	Internal Reference	Package Description	Package Option	Branding
AD5623RBCPZ-3250R7 <sup>1</sup>	-40°C to +105°C	±1 LSB INL	1.25 V	10-lead LFCSP WD	CP-10-9	D85
				_		
AD5623RBCPZ-3REEL7 <sup>1</sup>	−40°C to +105°C	±1 LSB INL	1.25 V	10-lead LFCSP_WD	CP-10-9	D85
AD5623RBRMZ-3 <sup>1</sup>	−40°C to +105°C	±1 LSB INL	1.25 V	10-lead MSOP	RM-10	D85
AD5623RBRMZ-3REEL7 <sup>1</sup>	-40°C to +105°C	±1 LSB INL	1.25 V	10-lead MSOP	RM-10	D85
AD5623RBRMZ-5 <sup>1</sup>	-40°C to +105°C	±1 LSB INL	2.5 V	10-lead MSOP	RM-10	D86
AD5623RBRMZ-5REEL7 <sup>1</sup>	-40°C to +105°C	±1 LSB INL	2.5 V	10-lead MSOP	RM-10	D86
AD5643RBRMZ-3 <sup>1</sup>	−40°C to +105°C	±4 LSB INL	1.25 V	10-lead MSOP	RM-10	D81
AD5643RBRMZ-3REEL7 <sup>1</sup>	-40°C to +105°C	±4 LSB INL	1.25 V	10-lead MSOP	RM-10	D81
AD5643RBRMZ-5 <sup>1</sup>	-40°C to +105°C	±4 LSB INL	2.5 V	10-lead MSOP	RM-10	D7Q
AD5643RBRMZ-5REEL7 <sup>1</sup>	-40°C to +105°C	±4 LSB INL	2.5 V	10-lead MSOP	RM-10	D7Q
AD5663RBCPZ-3250R7 <sup>1</sup>	−40°C to +105°C	±16 LSB INL	1.25 V	10-lead LFCSP_WD	CP-10-9	D7S
AD5663RBCPZ-3REEL7 <sup>1</sup>	−40°C to +105°C	±16 LSB INL	1.25 V	10-lead LFCSP_WD	CP-10-9	D7S
AD5663RBRMZ-3 <sup>1</sup>	-40°C to +105°C	±16 LSB INL	1.25 V	10-lead MSOP	RM-10	D7S
AD5663RBRMZ-3REEL7 <sup>1</sup>	-40°C to +105°C	±16 LSB INL	1.25 V	10-lead MSOP	RM-10	D7S
AD5663RBRMZ-5 <sup>1</sup>	-40°C to +105°C	±16 LSB INL	2.5 V	10-lead MSOP	RM-10	D7H
AD5663RBRMZ-5REEL7 <sup>1</sup>	-40°C to +105°C	±16 LSB INL	2.5 V	10-lead MSOP	RM-10	D7H
