500ksps, 12-Bit ADCs with Track/Hold and Reference

MAX120/MAX122**General Description**

The MAX120 and MAX122 complete, BiCMOS, sampling 12-bit analog-to-digital converters (ADCs) combine an on-chip track/hold (T/H) and a low-drift voltage reference with fast conversion speeds and low power consumption. The T/H's 350ns acquisition time combined with the MAX120's 1.6 μ s conversion time results in throughput rates as high as 500k samples per second (ksps). Throughput rates of 333ksps are possible with the 2.6 μ s conversion time of the MAX122.

The MAX120/MAX122 accept analog input voltages from -5V to +5V. The only external components needed are decoupling capacitors for the power-supply and reference voltages. The MAX120 operates with clocks in the 0.1MHz to 8MHz frequency range. The MAX122 accepts 0.1MHz to 5MHz clock frequencies.

The MAX120/MAX122 employ a standard microprocessor (μ P) interface. Three-state data outputs are configured to operate with 12-bit data buses. Data-access and bus-release timing specifications are compatible with most popular μ Ps without resorting to wait states. In addition, the MAX120/MAX122 can interface directly to a first in, first out (FIFO) buffer, virtually eliminating μ P interrupt overhead. All logic inputs and outputs are TTL/CMOS compatible. For applications requiring a serial interface, refer to the new MAX121.

Applications

Digital-Signal Processing
Audio and Telecom Processing
Speech Recognition and Synthesis
High-Speed Data Acquisition
Spectrum Analysis
Data Logging Systems

Pin Configuration**Features**

- ◆ 12-Bit Resolution
- ◆ No Missing Codes Over Temperature
- ◆ 20ppm/°C -5V Internal Reference
- ◆ 1.6 μ s Conversion Time/500ksps Throughput (MAX120)
- ◆ 2.6 μ s Conversion Time/333ksps Throughput (MAX122)
- ◆ Low Noise and Distortion:
70 dB Min SINAD;
-77 dB Max THD (MAX122)
- ◆ Low Power Dissipation: 210mW
- ◆ Separate Track/Hold Control Input
- ◆ Continuous-Conversion Mode Available
- ◆ $\pm$ 5V Input Range, Overvoltage Tolerant to $\pm$ 15V
- ◆ 24-Pin Narrow DIP, Wide SO and SSOP Packages

Note 7: Control inputs specified with t_r = t_f = 5ns (10% to 90% of +5V) and timed from a 1.6V voltage level. Output delays are measured to +0.8V if going low, or +2.4V if going high. For bus-relinquish time, a change of 0.5V is measured. See Figures 1 and 2 for load circuits.

Note 8: For design guidance only, not tested.

Pin Description

PIN	NAME	FUNCTION
1	MODE	Mode Input - hard-wire to set operational mode. V _{DD} : Single conversion, INT Output OPEN: Single conversion, BUSY Output DGND: Continuous conversions, BUSY Output
2	V _{SS}	Negative Power Supply, -12V or -15V
3	V _{DD}	Positive Power Supply, +5V
4	A _{IN}	Sampling Analog Input, ±5V bipolar input range
5	VREF	-5V Reference Output - bypass to AGND with 22μF 0.1μF

500kps, 12-Bit ADCs with Track/Hold and Reference

Pin Description (continued)

MAX120/MAX122

PIN	NAME	FUNCTION
6	AGND	Analog Ground
7-11, 13-19	D11-D0	Three-State Data Outputs D11 (MSB) to D0 (LSB)
12	DGND	Digital Ground
20	CONVST	Convert Start Input initiates conversions on its falling edge.
21	CLKIN	Clock Input. Drive with TTL-compatible clock from 0.1MHz to 8MHz (MAX120), 0.1MHz to 5MHz (MAX122).
22	INT/BUSY	Interrupt or Busy Output indicates converter status. If MODE is connected to V _{DD} , configure for an INT output. If MODE is open or connected to DGND, configure for a BUSY output. See operational diagrams.
23	CS	Chip Select Input - active low. When $\overline{RD}$ is low, enables the three-state outputs. If $\overline{CONVST}$ and $\overline{RD}$ are low, a conversion is initiated on the falling edge of CS.
24	$\overline{RD}$	Read Input - active low. When $\overline{CS}$ is low, $\overline{RD}$ enables the three-state outputs. If $\overline{CONVST}$ and $\overline{CS}$ are low, a conversion is initiated on the falling edge of $\overline{RD}$.

Detailed Description

ADC Operation

The MAX120/MAX122 use successive approximation and input T/H circuitry to convert an analog signal to a series of 12-bit digital-output codes. The control logic interfaces easily to most μ Ps, requiring only a few passive components for most applications. The T/H does not require an external capacitor. Figure 3 shows the MAX120/MAX122 in the simplest operational configuration.

Analog Input Track/Hold

Figure 4 shows the equivalent input circuit, illustrating the sampling architecture of the ADC's analog comparator. An internal buffer charges the hold capacitor to minimize the required acquisition time between conversions. The analog input appears as a $6k\Omega$ resistor in parallel with a $10pF$ capacitor.

Between conversions, the buffer input is connected to AIN through the input resistance. When a conversion starts, the buffer input disconnects from AIN, thus sampling the input. At the end of the conversion, the buffer input reconnects to AIN, and the hold capacitor once again charges to the input voltage.

The T/H is in tracking mode whenever a conversion is NOT in progress. Hold mode starts approximately 10ns after a conversion is initiated. Variation in this delay from one conversion to the next (aperture jitter) is typically 30ps. Figures 7 through 11 detail the T/H mode and interface timing for the various interface modes.

Figure 1. Load Circuits for Access Time

Figure 2. Load Circuits for Bus-Relinquish Time

MAX120/MAX122

An external reference voltage can be used to overdrive the MAX120/MAX122's internal reference if it ranges from -5.05V to -5.10V and is capable of sinking a minimum of 5mA. The external VREF bypass capacitors are still required.

For a conversion time of 13 clock cycles, the convert start input(s) should go low at least 50ns before CLKIN's next rising edge. For a conversion time of 14 clock cycles, the convert start input(s) should go low within 10ns of CLKIN's next rising edge. If the convert start input(s) go low from 10ns to 50ns before CLKIN's next rising edge, the number of clock cycles required is undefined and can be either 13 or 14. For best analog performance, synchronize the convert start inputs with the clock input.

MAX120/MAX122

Figure 5. Clock and Control Synchronization

Figure 7. Full-Control Mode (Mode 1)

Figure 6. Data-Access and Bus-Relinquish Timing

Output Data Format

The conversion result is output on a 12-bit data bus with a 75ns data-access time. The output data format is two's-complement. The three input control signals (CS, RD, and CONVST), the INT/BUSY converter status output, and the 12 bits of output data can interface directly to a 16-bit data bus. See Figure 6 for data-access timing.

Timing and Control

The MAX120/MAX122 have five operational modes as outlined in Figures 7-11 and discussed in the *Operating Modes* section.

Full-control mode (mode 1) provides maximum control to the user for convert start and data-read operations.

Full-control mode is for μ Ps with or without wait-state capability. Stand-alone mode (mode 2) and continuous-conversion mode (mode 5) are for systems without μ Ps, or for μ P-based systems where the ADC and the μ P are linked through first in, first out (FIFO) buffers or direct memory access (DMA) ports. Slow-memory mode (mode 3) is intended for μ Ps that can be forced into a wait state during the ADC's conversion time. ROM mode (mode 4) is for μ Ps that cannot be forced into a wait state.

In all five operating modes, the start of a conversion is controlled by one of three digital inputs: CONVST, RD, or CS. Figure 12 shows the logic equivalent for the conversion circuitry. In any operating mode, CONVST must be low for a conversion to occur. Once the conversion is in progress, it cannot be restarted.

Read operations are controlled by RD and CS. Both of these digital inputs must be low to read output data. The INT/BUSY output indicates the converter's status and determines when the data from the most recent conversion is available. The MODE input configures the INT/BUSY output as follows:

IF MODE = VDD, INT/BUSY functions as an INTERRUPT output. In this configuration, INT/BUSY goes low when the conversion is complete and returns high after the conversion data has been read.

IF MODE is left open or tied to DGND, INT/BUSY functions as a BUSY output. In this case, INT/BUSY goes low at the start of a conversion and remains low until the conversion is complete and the data is available at D0-D11.

500ksps, 12-Bit ADCs with Track/Hold and Reference

Figure 8. Stand-Alone Mode (Mode 2)

Figure 9. Slow-Memory Mode (Mode 3)

Initialization After Power-Up

On power-up, the first MAX120/MAX122 conversion is valid if the following conditions are met:

- 1) Allow 14 clock cycles for the internal T/H to enter the track mode, plus a minimum of 350ns in the track mode for the data-acquisition time.
- 2) Make sure the reference voltage has settled. Allow 0.5ms for each 1 μ F of reference bypass capacitance (11ms for a 22 μ F capacitor).

Operating Modes

Mode 1: (Full-Control Mode)

Figure 7 shows the timing diagram for full-control mode (mode 1). In this mode, the μ P controls the conversion-start and data-read operations independently.

A falling edge on $\overline{\text{CONVST}}$ places the T/H into hold mode and starts a conversion in the SAR. The conversion is complete in 13 or 14 clock cycles as discussed in the *Clock and Control Synchronization* section. A change in the $\overline{\text{INT/BUSY}}$ output state signals the end of a conversion as follows:

If $\text{MODE} = \text{VDD}$, the end of conversion is signaled by the $\overline{\text{INT/BUSY}}$ output falling edge.

If $\text{MODE} = \text{OPEN}$ or DGND , the $\overline{\text{INT/BUSY}}$ output goes low while the conversion is in progress and returns high when the conversion is complete.

When the conversion is complete, the data can be read without initiating a new conversion by pulling $\overline{\text{RD}}$ and $\overline{\text{CS}}$ low and leaving $\overline{\text{CONVST}}$ high. To start a new conversion without reading data, $\overline{\text{RD}}$ and $\overline{\text{CS}}$ should remain high while $\overline{\text{CONVST}}$ is driven low. To simultaneously read data and initiate a new conversion, $\overline{\text{CONVST}}$, $\overline{\text{RD}}$, and $\overline{\text{CS}}$ should all be pulled low. Note: Allow at least 350ns for T/H acquisition time between the end of one conversion and the beginning of the next.

Mode 2: Stand-Alone Operation ($\text{MODE} = \text{OPEN}$, $\overline{\text{RD}} = \overline{\text{CS}} = \text{DGND}$)

For systems that do not use or require full-bus interfacing, the MAX120/MAX122 can be operated in stand-alone mode directly linked to memory through DMA ports or a FIFO buffer. In stand-alone mode, a conversion is initiated by a falling edge on $\overline{\text{CONVST}}$. The data outputs are always enabled; data changes at the end of a conversion as indicated by a rising edge on $\overline{\text{INT/BUSY}}$. See Figure 8 for stand-alone mode timing.

Mode 3: Slow-Memory Mode ($\overline{\text{CONVST}} = \text{GND}$, $\text{MODE} = \text{OPEN}$)

Taking $\overline{\text{RD}}$ and $\overline{\text{CS}}$ low places the T/H into hold mode and starts a conversion. $\overline{\text{INT/BUSY}}$ remains low while the conversion is in progress and can be used as a wait input to the μ P. Data from the previous conversion appears on the data bus until the conversion end is indicated by $\overline{\text{INT/BUSY}}$. See Figure 9 for slow-memory mode timing.

500kps, 12-Bit ADCs with Track/Hold and Reference

Figure 10. ROM Mode (Mode 4)

Figure 11. Continuous-Conversion Mode (Mode 5)

Mode 4: ROM Mode (MODE = OPEN, CONVST = GND)

In ROM mode, the MAX120/MAX122 behave like a fast-access memory location and avoid placing the μ P into a wait state. Pulling RD and CS low places the T/H in hold mode, starts a conversion, and reads data from the previous conversion. Data from the first read in a sequence is often disregarded when this interface mode is used. A second read operation accesses the first conversion's result and also starts a new conversion. The time between successive read operations must be longer than the sum of the T/H acquisition time and the MAX120/MAX122 conversion time. See Figure 10 for ROM-mode timing.

Mode 5: Continuous-Conversion Mode (CONVST = RD = CS = MODE = GND)

For systems that do not use or require full-bus interfacing, the MAX120/MAX122 can operate in continuous-conver-

Figure 12. Conversion-Control Logic

sion mode, directly linked to memory through DMA ports or a FIFO buffer. In this mode, conversions are performed continuously at the rate of one conversion for every 14 clock cycles, which includes 2 clock cycles for the T/H acquisition time. To satisfy the 350ns minimum acquisition time requirement within 2 clock cycles, the MAX120's maximum clock frequency is 6MHz when operating in mode 5.

The data outputs are always enabled and "new" data appears on the output bus at the end of a conversion as indicated by the INT/BUSY output rising edge. The MODE input should be hard-wired to GND. Pulling CS, RD, or CONVST high stops conversions. See Figure 11 for continuous-conversion mode timing.

Applications Information

Using FIFO Buffers

Using FIFO memory to buffer blocks of data from the MAX120 reduces μ P interrupt overhead time by enabling the μ P to process data while the MAX120, unassisted, writes conversion results to the FIFO. To retrieve a block of data, the μ P reads from the FIFO via a read-interrupt cycle. Read and write operations for the FIFO are completely asynchronous. Figure 13 shows the MAX120 operating in continuous-conversion mode (mode 5), writing data directly into the two IDT7200 256 x 9 FIFO buffers at the rate of 428kps. The μ P is interrupted to read the accumulated data by the FIFO's half-full (HF) flag approximately three times per millisecond. For operation at 500kps, use an 8MHz clock, and pulse CONVST at 500kHz. The full flag (FF) indicates that the FIFO is full. If this flag is ignored, data may be lost. If necessary, conversions can be inhibited by pulling CS, RD, or CONVST high. The FIFO's read cycle times are as fast as 15ns, satisfying most system speed requirements. The RESET input resets all data in the FIFO to zero.

500ksps, 12-Bit ADCs with Track/Hold and Reference

Figure 13. Using MAX120 with FIFO Memory

For synchronous operation, the $\overline{\text{CONVST}}$ pin may be used to initiate conversions, as described in the *Operating Modes* section (Mode 2: Stand-Alone Operation).

Digital-Bus Noise

If the ADC's data bus is active during a conversion, coupling from the data pins to the ADC comparator can cause errors. Using slow-memory mode (mode 3) avoids this problem by placing the μP in a wait state during the conversion. If the data bus is active during the conversion in either mode 1 or 4, use three-state drivers to isolate the bus from the ADC.

In ROM mode (mode 4), considerable digital noise is generated in the ADC when $\overline{\text{RD}}$ or $\overline{\text{CS}}$ go high, disabling the output buffers after a conversion is started. This noise can cause errors if it occurs at the same instant the SAR latches a comparator decision. To avoid this problem, $\overline{\text{RD}}$ and $\overline{\text{CS}}$ should be active for less than 1 clock cycle. If this is not possible, $\overline{\text{RD}}$ or $\overline{\text{CS}}$ should go high coinciding with CLKIN's falling edge, since the comparator output is always latched at CLKIN's rising edge.

Layout, Grounding, and Bypassing

For best system performance, use printed circuit boards with separate analog and digital ground planes. Wire-wrap boards are not recommended. The two ground planes should be tied together at the low-impedance power-supply source, as shown in Figure 14.

The board layout should ensure that digital and analog signal lines are kept separate from each other as much as possible. Do not run analog and digital (especially clock) lines parallel to one another.

The ADC's high-speed comparator is sensitive to high-frequency noise in the VDD and VSS power supplies. Bypass these supplies to the analog ground plane with 0.1 μF and 10 μF bypass capacitors. Minimize capacitor lead lengths for best noise rejection. If the +5V power supply is very noisy, connect a 5 Ω resistor, as shown in Figure 14. Figure 15 shows the negative power-supply (VSS) rejection vs. frequency. Figure 16 shows the positive power-supply (VDD) rejection vs. frequency, with and without the optional 5 Ω resistor.

500kps, 12-Bit ADCs with Track/Hold and Reference

MAX120/MAX122

Figure 14. Power-Supply Grounding

Figure 15. V_{SS} Power-Supply Rejection vs. Frequency

Gain and Offset Adjustment

Figure 17 plots the bipolar input/output transfer function for the MAX120/MAX122. Code transitions occur halfway between successive integer LSB values. Output coding is twos-complement binary with $1\text{LSB} = 2.44\text{mV}$ ($10\text{V}/4096$).

In applications where gain (full-scale range) adjustment is required, Figure 18's circuit can be used. If both offset and gain (full-scale range) need adjustment, either of the circuits in Figures 19 and 20 can be used. Offset should be adjusted before gain for either of these circuits.

Figure 16. V_{DD} Power-Supply Rejection vs. Frequency

To adjust bipolar offset with Figure 19's circuit, apply $+1/2\text{LSB}$ (0.61mV) to the noninverting amplifier input and adjust $R4$ for output-code flicker between 0000 0000 and 0000 0000 0001. For full scale, apply $\text{FS} - 1/2\text{LSB}$ (2.4988V) to the amplifier input and adjust $R2$ so the output code flickers between 0111 1111 1110 and 0111 1111 1111. There may be some interaction between these adjustments. The MAX120/MAX122 transfer function used in conjunction with Figure 19's circuit is the same as Figure 17, except the full-scale range is reduced to 2.5V .

To adjust bipolar offset with Figure 20's circuit, apply $-1/2\text{LSB}$ (-1.22mV) at V_{IN} and adjust $R5$ for output-code flicker between 0000 0000 0000 and 0000 0000 0001. For gain adjustment, apply $-\text{FS} + 1/2\text{LSB}$ (-4.9951V) at V_{IN} and adjust $R1$ so the output code flickers between 0111 1111 1110 and 0111 1111 1111. As with Figure 20's circuit, the offset and gain adjustments may interact. Figure 21 plots the transfer function for Figure 20's circuit.

Dynamic Performance

High-speed sampling capability and 500kps throughput (333kps for the MAX122) make the MAX120/MAX122 ideal for wideband-signal processing. To support these and other related applications, fast fourier transform (FFT) test techniques are used to guarantee the ADC's dynamic frequency response, distortion, and noise at the rated throughput. Specifically, this involves applying a low-distortion sine wave to the ADC input and recording the digital conversion results for a specified time. The data is then analyzed using an FFT algorithm, which determines its spectral content.

Figure 18. Trim Circuit for Gain Only

Figure 20. Offset and Gain Adjustment (Inverting)

ADCs have traditionally been evaluated by specifications such as zero and full-scale error, integral nonlinearity (INL), and differential nonlinearity (DNL). Such parameters are widely accepted for specifying performance with DC and slowly varying signals, but are less useful in signal processing applications where the ADC's impact on the system transfer function is the main concern. The significance of various DC errors does not translate well to the dynamic case, so different tests are required.

Signal-to-Noise Ratio and Effective Number of Bits

The signal-to-noise plus distortion ratio (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to the RMS amplitude of all other ADC output signals. The output band is limited to frequencies above DC and below one-half the ADC sample rate.

The theoretical minimum ADC noise is caused by quantization error and is a direct result of the ADC's resolution: $SNR = (6.02N + 1.76)dB$, where N is the number of bits of resolution. A perfect 12-bit ADC can, therefore, do no better than 74dB. An FFT plot shows the output level in various spectral bands. Figure 22 shows the result of sampling a pure 100kHz sinusoid at a 500ksps rate with the MAX120.

By transposing the equation that converts resolution to SNR, we can, from the measured SINAD, determine the effective resolution (or effective number of bits) the ADC provides: $N = (SINAD - 1.76)/6.02$. Figure 22 shows the effective number of bits as a function of the input frequency for the MAX120. The MAX122 performs similarly.

Total Harmonic Distortion

If a pure sine wave is sampled by an ADC at greater than the Nyquist frequency, the nonlinearities in the ADC's transfer function create harmonics of the input frequency in the sampled output data.

Total harmonic distortion (THD) is the ratio of the RMS sum of all harmonics (in the frequency band above DC and below one-half the sample rate, but not including the DC component) to the RMS amplitude of the fundamental frequency. This is expressed as follows:

$$THD = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + \dots + V_N^2}}{V_1}$$

where V_1 is the fundamental RMS amplitude, and V_2 to V_N are the amplitudes of the 2nd through Nth harmonics. The THD specification in the *Electrical Characteristics* table includes the 2nd through 5th harmonics.

Intermodulation Distortion

If the ADC input signal consists of more than one spectral component, the ADC transfer function nonlinearities produce intermodulation distortion (IMD) in addition to THD. IMD is the change in one sinusoidal input caused by the presence of another sinusoidal input at a different frequency.

If two pure sine waves of frequency f_a and f_b are applied to the ADC input, nonlinearities in the ADC transfer function create distortion products at sum and difference frequencies of $m f_a \pm n f_b$, where m and $n = 0, 1, 2, 3$, etc. THD includes those distortion products with m or n equal to zero. Intermodulation distortion consists of all distortion products for which neither m nor n equal zero. For example, the 2nd-order IMD terms include $(f_a + f_b)$ and $(f_a - f_b)$ while the 3rd-order IMD terms include $(2f_a + f_b)$, $(2f_a - f_b)$, $(f_a + 2f_b)$, and $(f_a - 2f_b)$.

If the two input sine waves are equal in magnitude, the value (in decibels) of the 2nd-order IMD products can be expressed by the following formula:

$$IMD(f_a \pm f_b) = 20 \log \left[\frac{\text{amplitude at } (f_a \pm f_b)}{\text{amplitude at } f_a} \right]$$

Spurious-Free Dynamic Range

Spurious-free dynamic range is the ratio of the fundamental RMS amplitude to the amplitude of the next largest spectral component (in the frequency band above DC and below one-half the sample rate). Usually the next largest spectral component occurs at some harmonic of the input frequency. However, if the ADC is exceptionally linear, it may occur only at a random peak in the ADC's noise floor.
