

- Speed of Bipolar FCT, AS, and S, With Significantly Reduced Power Consumption
- Digital Design Avoids Analog Compensation Errors
- Easily Cascadable for Higher-Order Loops
- Useful Frequency Range
 - DC to 110 MHz Typical (K CLK)
 - DC to 70 MHz Typical (I/D CLK)
- Dynamically Variable Bandwidth
- Very Narrow Bandwidth Attainable
- Power-On Reset
- Output Capability
 - Standard: XORPD OUT, ECPD OUT
 - Bus Driver: I/D OUT
- SCR Latch-Up-Resistant CMOS Process and Circuit Design
- Balanced Propagation Delays
- ESD Protection Exceeds 2000 V Per MIL-STD-883, Method 3015

description/ordering information

The CD74ACT297 provides a simple, cost-effective solution to high-accuracy, digital, phase-locked-loop applications. This device contains all the necessary circuits, with the exception of the divide-by-N counter, to build first-order phase-locked loops as shown in Figure 1.

Both exclusive-OR phase detectors (XORPDs) and edge-controlled (ECPD) phase detectors are provided for maximum flexibility.

Proper partitioning of the loop function, with many of the building blocks external to the package, makes it easy for the designer to incorporate ripple cancellation or to cascade to higher-order phase-locked loops.

The length of the up/down K counter is digitally programmable according to the K-counter function table. With A, B, C, and D all low, the K counter is disabled. With A high and B, C, and D low, the K counter is only three stages long, which widens the bandwidth, or capture range, and shortens the lock time of the loop. When A, B, C, and D are programmed high, the K counter becomes 17 stages long, which narrows the bandwidth, or capture range, and lengthens the lock time. Real-time control of loop bandwidth by manipulating the A-through-D inputs can maximize the overall performance of the digital phase-locked loop.

ORDERING INFORMATION

T _A	PACKAGE [†]		ORDERABLE PART NUMBER	TOP-SIDE MARKING
–55°C to 125°C	SOIC – M	Tube	CD74ACT297M	ACT297M
		Tape and reel	CD74ACT297M96	

[†] Package drawings, standard packing quantities, thermal data, symbolization, and PCB design guidelines are available at www.ti.com/sc/package.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

DIGITAL PHASE-LOCKED LOOP

SCHS297D – AUGUST 1998 – REVISED JUNE 2002

description/ordering information (continued)

This device performs the classic first-order phase-locked-loop function without using analog components. The accuracy of the digital phase-locked loop (DPLL) is not affected by V_{CC} and temperature variations, but depends solely on accuracies of the K clock (K CLK), increment/decrement clock (I/D CLK), and loop propagation delays. The I/D clock frequency and the divide-by-N modulus determine the center frequency of the DPLL. The center frequency is defined by the relationship $f_c = \text{I/D clock}/2N$ (Hz).

CD74ACT297 DIGITAL PHASE-LOCKED LOOP

SCHS297D – AUGUST 1998 – REVISED JUNE 2002

functional block diagram

detailed description

The phase detector generates an error-signal waveform that, at zero phase error, is a 50% duty-cycle square wave. At the limits of linear operation, the phase-detector output is either high or low all of the time, depending on the direction of the phase error ($\phi_{in} - \phi_{out}$). Within these limits, the phase-detector output varies linearly with the input phase error according to the gain k_d , which is expressed in terms of phase-detector output per cycle of phase error. The phase-detector output can be varied between ± 1 according to the relation:

$$\text{Phase-detector output} = \frac{\% \text{ high} - \% \text{ low}}{100} \quad (1)$$

The output of the phase detector is $k_d \phi_e$, where the phase error $\phi_e = \phi_{in} - \phi_{out}$.

XORPD and ECPD are commonly used digital types. The ECPD is more complex than the XORPD, but can be described generally as a circuit that changes states on one of the transitions of its inputs. For an XORPD, $k_d = 4$, because its output remains high (PD output = 1) for a phase error of one-fourth cycle. Similarly, for the ECPD, $k_d = 2$, because its output remains high for a phase error of one-half cycle. The type of phase detector determines the zero-phase-error point, i.e., the phase separation of the phase-detector inputs for ϕ_e is defined to be zero. For the basic DPLL system of Figure 2, $\phi_e = 0$ when the phase-detector output is a square wave. The XORPD inputs are one-fourth cycle out of phase for zero phase error. For the ECPD, $\phi_e = 0$ when the inputs are one-half cycle out of phase.

Figure 2. DPLL Using Exclusive-OR Phase Detection

The phase-detector output controls the up/down input to the K counter. The counter is clocked by input frequency Mf_c , which is a multiple M of the loop center frequency f_c . When the K counter recycles up, it generates a carry pulse. Recycling while counting down generates a borrow pulse. If the carry and borrow outputs are conceptually combined into one output that is positive for a carry and negative for a borrow, and if the K counter is considered as a frequency divider with the ratio Mf_c/K , the output of the K counter equals the input frequency multiplied by the division ratio. Thus, the output from the K counter is $k_d \phi_e Mf_c/K$.

The carry and borrow pulses go to the increment/decrement (I/D) circuit, which, in the absence of any carry or borrow pulse, has an output that is one-half of the input clock (I/D CLK). The input clock is just a multiple ($2N$) of the loop center frequency. In response to a carry or borrow pulse, the I/D circuit either adds or deletes a pulse at I/D OUT. Thus, the output of the I/D circuit is $Nf_c + (k_d \phi_e Mf_c)/2K$.

The output of the N counter (or the output of the phase-locked loop) is:

$$f_o = f_c + (k_d \phi_e Mf_c)/2KN \quad (2)$$

When this result is compared to the equation for a first-order analog phase-locked loop, the digital equivalent of the gain of the VCO is $Mf_c/2KN$, or f_c/K for $M = 2N$.

SCHS297D – AUGUST 1998 – REVISED JUNE 2002

Thus, the simple first-order phase-locked loop with an adjustable K counter is the equivalent of an analog phase-locked loop with a programmable VCO gain.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)[†]

Supply voltage range, V_{CC}	−0.5 V to 6 V
DC input diode current, I_{IK} ($V_I < -0.5$ V or $V_I > V_{CC} + 0.5$ V)	±20 mA
DC input diode current, I_{OK} ($V_O < -0.5$ V or $V_O > V_{CC} + 0.5$ V)	±50 mA
DC output source or sink current per output pin, I_O ($V_O > -0.5$ V or $V_O < V_{CC} + 0.5$ V)	±50 mA
Continuous current through V_{CC} or GND (see Note 1)	±100 mA
Package thermal impedance, θ_{JA} (see Note 2)	73°C/W
Storage temperature range, T_{stg}	−65°C to 150°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTES: 1. For up to four outputs per device, add ± 25 mA for each additional output.
2. The package thermal impedance is calculated in accordance with JEDEC 51-7.

recommended operating conditions

		MIN	MAX	UNIT
V _{CC}	Supply voltage	4.5	5.5	V
V _{IH}	High-level input voltage	2		V

PARAMETER MEASUREMENT INFORMATION

- NOTES:
- A. C_L includes probe and jig capacitance.
 - B. Waveform 1 is for an output with internal conditions such that the output is low except when disabled by the output control. Waveform 2 is for an output with internal conditions such that the output is high except when disabled by the output control.
 - C. All input pulses are supplied by generators having the following characteristics: $PRR \leq 1 \text{ MHz}$, $Z_O = 50 \Omega$, $t_r = 3 \text{ ns}$, $t_f = 3 \text{ ns}$.
 - D. The outputs are measured one at a time with one input transition per measurement.
