Pin Descriptions (Refer to the Block Diagrams)

Pins	Description
1, 12	SUB: These pins make electrical contact with the substrate of the die. Ground them. For best thermal performance, ground them to the same large, uninterrupted copper plane as the PGND pins.
2	SLEEP LOGIC: Use this logic input to select the conversion mode; low selects PWM, high selects sleep, and high impedance (open) permits the LM2650 to move freely and automatically between the modes, using PWM for moderate to heavy loads and sleep for light loads.
3, 4, 9, 10	PGND: The ground return of the power stage. The power stage consists of the two power switches Q1 and Q2, the gate drivers DH and DL, and the linear voltage regulators VRegH and VRegL. For best electrical and thermal performance, ground these pins to a large, uninterrupted copper plane.
5, 8	SW: The output node of the power stage. It swings from slightly below ground to slightly below the voltage to PV_{IN} . To minimize the effects of switching noise on nearby circuitry, keep all traces originating from SW short and to the point. Route all traces carrying signals well away from the SW traces.
6, 7	PV_{IN}: The positive supply rail of the power stage. Bypass each PV_{IN} pin to PGND with a 0.1 μF capacitor. Use capacitors having low ESL and low ESR, and locate them close to the IC.
11	BOOT: The positive supply rail of the high-side gate driver DH. Connect a 0.1 μF capacitor from this node to SW. Bootstrapping action creates a supply rail about 9V above that at PV_{IN} , and DH uses this rail to override the gate of the NMOS power FET Q1. Overriding ensures low $R_{DS(on)}$.
13	FB: The feedback input.
14	V_{DD}: An internal regulator steps the input voltage down to a 4V rail used by the signal-level circuitry. V_{DD} is the output node of this regulator. Bypass V_{DD} to GND close to the IC with a 0.2 μF capacitor.
15	COMP: The inverting input of the error amplifier EA.
16	EA OUT: The output node of the error amplifier EA.
17	SS: The soft start node. Connect a capacitor from SS to GND.
18	GND: The ground return of the signal-level circuitry.
19	V_{IN}: The positive supply rail of the internal 4V regulator. Bypass V_{IN} to GND close to the IC with a 0.1 μF capacitor.
20	FREQ ADJ: The LM2650 switches at a nominal 90 kHz. Connect a resistor between FREQ ADJ and GND to adjust the frequency up from the nominal. Use the graph under Typical performance Characteristics to select the resistor.
21	SYNC: The synchronization input. If the switching frequency is to be synchronized with an external clock signal, apply the clock signal here. Ground if not used.
22	SD: Use this logic input to control shutdown; pull low for operation, high for shutdown.
23	SLEEP OUT ADJ (SOA): The value of the resistor connected between SIA and ground programs the sleep-in threshold. Higher values program lower thresholds.
24	SLEEP IN ADJ (SIA): The value of the resistor connected between SIA and ground programs the sleep-in threshold. Higher values program lower thresholds.

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

(All voltages are referenced to the PGND and GND pins.)

DC Voltage at PV_{IN} and V_{IN} 20V

DC Voltage at SD, SLEEP LOGIC and SYNC 15V

DC current into SW $\pm 7.5A$

Junction Temperature Limited by the IC

DC Power Dissipation (Note 2) 1.28W

Storage Temperature $-65^{\circ}C$ to $+150^{\circ}C$

Soldering Time, Temperature (Note 3)

Wave (4 seconds) $260^{\circ}C$

Infrared (10 seconds) $240^{\circ}C$

Vapor Phase (75 seconds) $219^{\circ}C$

ESD Susceptibility (Note 4) 1.3 kV

Operating Ratings (Note 1)

Supply Voltage Range (PV_{IN} and V_{IN}) 4.5V to 18V

Junction Temperature Range $-40^{\circ}C$ to $+125^{\circ}C$

Electrical Characteristics

$V_{PVIN} = 15V$, $V_{SLEEP\ LOGIC} = 0V$ and $V_{SD} = 0V$ unless superseded under **Conditions**. Typical values appearing in plain type apply for $T_A = T_J = +25^{\circ}C$. Limits appearing in **boldface** type apply over the full junction temperature range shown under **Operating Ratings**.

Symbol	Parameter	Conditions	Typ (Note 5)	Limit (Note 6)	Units

T_{SD}	T_J for Thermal Shutdown		170		$^\circ C$

Note 1: Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which the device operates correctly. Operating ratings do not imply guaranteed performance limits. For guaranteed performance limits and associated test conditions, see the Electrical Characteristics.

Note 2: This rating is calculated using the formula $P_{DCmax} = (T_{Jmax} - T_A) / \theta_{JA}$, where P_{DCmax} is the absolute maximum power dissipation, T_{Jmax} is the maximum junction temperature, and θ_{JA} is the junction to ambient thermal resistance of the package. The P_{DCmax} rating of 1.28W results from substituting $170^\circ C$, $70^\circ C$ and $78^\circ C/W$ for T_{Jmax} , T_A and θ_{JA} respectively. A θ_{JA} of $78^\circ C$ represents the worst condition of no heat sinking of the M24B small-outline package. Heat sinking allows the safe dissipation of more power. See Application Notes on thermal management. The LM2650 actively limits its junction temperature to about $170^\circ C$.

Note 3: For detailed information on soldering plastic small-outline packages, refer to the Packaging Databook published by National Semiconductor Corporation.

Note 4: ESD is applied using the human-body model, a 100pF capacitor discharged through a 1.5k Ω resistor.

Note 5: A typical is the center of characterization data taken at $T_A = T_J = 25^\circ C$.

Note 6: All limits are guaranteed. The guarantee is backed with 100% testing at $T_A = T_J = 125^\circ C$ and statistical correlation for room temperature and cold limits.

Note 7: V_{REF} is measured at SLEEP OUT ADJ.

Note 8: Quiescent current is the total current flowing into the P_{VIN} and V_{IN} pins. I_Q includes the current used to drive the gates of the two NMOS power FETs at the nominal switching frequency. I_{QS} includes no such current.

Note 9: Pulling 100 μA out of FREQ ADJ simulates adjusting the oscillator frequency with a 12.5 k Ω resistor connected from FREQ ADJ to GND. The sleep mode cannot be used at switching frequencies above 250 kHz.

Operation

OVERVIEW

The LM2650 uses two step-down conversion modes: fixed-frequency pulse-width modulation (PWM) and hysteretic. It moves freely and automatically between them, using PWM for moderate to heavy loads and hysteretic for light loads.

For clarity, separate block diagrams for each conversion mode have been included. See *Figure 1* and *Figure 2*. Blocks used in both modes appear in both diagrams with the same label. For example, both modes use the input buffer B. To keep the diagrams simple, most power supply rails have been omitted. R3, C10, R_C, C_C, C_B, L1, R1, R2, and C_{OUT} are outside the IC.

THE PWM CIRCUIT (*Figure 1*)

The PWM is a fixed-frequency, voltage-mode pulse-width modulator. It consists of four functional blocks: an input buffer, an error amplifier, a modulator, and a power stage.

1. The input buffer B: B is a voltage follower. A fraction of the output voltage is fed back to its noninverting input FB. Circumventing B by using the COMP input as the feedback input will cause the IC to malfunction.
2. The error amplifier EA: EA is a voltage amplifier. It subtracts the feedback voltage from the 1.25V reference and amplifies the difference to produce an error voltage for the control loop. For the purpose of loop compensation, EA is typically configured as an integrator. In this configuration, a capacitor C_C and a resistor R_C are connected in series between the inverting input COMP and the output terminal EA OUT. The capacitor and the internal 6.5kΩ resistor create a pole, while the capacitor and series resistor create a zero.
3. The modulator: The modulator is the heart of the PWM circuit. It consists of the 90 kHz oscillator, the voltage comparator C1, and output logic represented here as a simple SR latch.

The modulator generates a continuous stream of rectangular, signal-level. It generates the pulses at a fixed frequency, and it modulates or varies their widths in response to variations in the error voltage. The pulses appear at Q, the output of the SR latch. An increase in the error voltage results in a proportional increase in the pulse widths, and, conversely, a decrease in the error voltage results in a proportional decrease in the pulse widths.

The oscillator produces a 90 kHz sawtooth that ramps between 1V and 2V. At the beginning of each ramp, the oscillator sets the SR latch sending Q high. As the ramp voltage surpasses the error voltage, C1 resets the SR latch sending Q low. An increase in the error voltage increases the time between the setting and the resetting of the SR latch which, in turn, results in an equal increase in pulse widths: that is, an equal increase in the time Q spends high in each cycle. A decrease in the error voltage has the opposite effect on the pulse widths as it decreases the time between the setting and resetting of the SR latch.

4. The power stage: The power stage puts some punch between the output of the modulator by translating the stream of signal-level pulses generated by the modulator into a stream of power pulses that swing from ground up to the input voltage while sinking and sourcing as much as 3.5A. The power stage consists of two gate drivers DH and DL, two linear voltage regulators VRegH

and VRegL, and two NMOS power FETs Q1 and Q2.

The power pulses appear at the SW mode. When Q goes high, DL drives the gate of Q2 low turning Q23 off. While Q2 turns off, the SW potential may remain at just below ground as the body diode of Q2 conducts what was previously reverse current (source-to-drain) in Q2, or the SW potential may swing up to just above the input voltage as the body diode of Q1 conducts what was previously forward current (drain-to-source) in Q2. About 50 ns after Q goes high, DH drives the gate of Q1 high turning Q1 on. If the task remains, Q1 pulls the SW potential up, if not, Q1 simply takes over the conduction responsibility from its own body diode. When Q goes low, the inverse action occurs resulting in the SW potential swinging from the input voltage to the ground. The 50 ns delay between one switch beginning to turn off and the other switch beginning to turn on prevents the switches from "shooting through" directly from the input supply to the ground.

The PWM circuit drives the pulse stream into the low-pass filter made up of L1 and C_{OUT}. The filter passed the DC component of the stream and attenuates the AC components. The output of the filter is the DC voltage V_{OUT} superimposed with a small ripple voltage. Since the DC component of any periodic waveforms the average value of the waveform, V_{OUT} can be found using:

$$V_{OUT} = \frac{1}{T} \times \int_0^T v(t) dt. \quad (1)$$

Here T is the switching period in seconds V(t) is the pulse stream. Under DC steady-state conditions, (1) yields

$$V_{OUT} = V_{IN} \times \frac{t_{ON}}{T} = V_{IN} \times D. \quad (2)$$

Here V_{IN} is the input voltage, and therefore the height of the pulses, in volts, is the width of the pulses in seconds, and D is the ratio of t_{ON} to T, the duty or the duty cycle.

The output voltage is programmed using the resistive divider made up for R1 and R2,

$$V_{OUT} = 1.25 \times \left(1 + \frac{R1}{R2}\right). \quad (3)$$

As Q1 turns on, its source voltage swings up to just below the input voltage. The LM2650 uses a simple technique called "bootstrapping" to pull the positive supply rail of DH (at BOOT) up along with the source voltage of Q1, but to a voltage above the input voltage. Because the source of Q1 and the positive supply rail of DH make the same voltage swing together, DH maintains the positive gate-to-source voltage required to turn Q1 on. Q12 plays an active role in pulling the supply rail of DH up and is therefore said to pull itself up by its "bootstraps", thus the name of the technique and of the BOOT pin.

In the typical application, a capacitor CB is connected outside the IC between the BOOT and SW pins. When Q2 is on, the input supply charges CB through VRegH and the internal diode D.

THE HYSTERETIC CIRCUIT AND LOOP (*Figure 2*)

Except for C2, the hysteretic circuit borrows all its circuit blocks from the PWM circuit.

Operation (Continued)

The hysteretic comparator C2 is a voltage comparator with built-in hysteresis V_{HYST} of typically 30mV centered at 1.25V.

The diode D2 is the body diode of Q2. The hysteretic circuit uses D2 as a rectifier instead of switching Q2 as a synchronous rectifier.

When the load current drops below the prescribed sleep-in threshold, the LM2650 shuts down the PWM loop and starts up the hysteretic loop. The hysteretic loop supports light loads more efficiently because it uses less power to support its own operation; it uses less bias power because it's a simpler loop having less circuit blocks to bias, and it switches slower, so it incurs lower switching losses.

The hysteretic control loop does not switch at a constant frequency. Instead, it monitors V_{OUT} and switches only when V_{OUT} reaches either side of a narrow window centered on the desired output voltage. C2 directs the switching based on its reading of the feedback voltage. Switching in this manner yields a regulated voltage consisting of the desired output voltage and an AC ripple voltage. The magnitude of the AC component can be approximated using

$$V_{OUT_PP} = V_{HYST} \times \frac{(R1 + R2)}{R2}. \quad (4)$$

For example, with V_{OUT} set to 5V, V_{OUT_PP} is approximately 120mV,

$$V_{OUT_PP} = 0.03 \times \frac{(75 + 24.9)}{24.9} = 120 \text{ mV}. \quad (5)$$

When it starts up, the hysteretic loop turns Q1 on. While Q1 is on, the input power supply charges C_{OUT} and supplies current to the load. Current from the supply reaches C and the load via the series path provided by Q1 and L1. As the feedback voltage just surpasses the upper hysteretic threshold of C2, the output of C2 changes from high to low, and HD responds by pulling the gate of Q1 down turning Q1 off. As Q1 turns off, L1 generates a negative-going voltage transient that D2 clamps at just below ground. D2 remains on only

briefly as the current in L1 runs out. While both Q1 and D2 are off, C_{OUT} alone supplies current to the load. As the feedback voltage just surpasses the lower hysteretic threshold of C2, the output of C2 changes states from low to high, and DH responds by pulling the gate of Q1 up turning Q1 on and starting the hysteretic cycle over.

Note that as the load current decreases, it takes increasingly longer periods for the load current to discharge C_{OUT} through the hysteretic window, and as the load current increases, the periods become even shorter. It can be seen from the above observation that the switching frequency of the hysteretic loop varies as the load varies. The switching frequency can be approximated using

$$f = \frac{I}{(C_{OUT} \times V_{OUT_PP})}. \quad (6)$$

Here f is the switching frequency in hertz, I is the load current in amperes, C_{OUT} is the value of the capacitor in farads, and V_{OUT_PP} is the magnitude of the AC ripple voltage in volts. Typical switching frequencies range anywhere from a few hertz for very light loads to a few thousand hertz for light loads bordering on the moderate level.

Application Circuits

Figure 4 is a schematic of the typical application circuit. Use the component values shown in the figure and those contained in Table 1 to build a 5V, 3A, or 3.3V, 3A step-down DC/DC converter. As with the design of any DC/DC converter, the design of these circuits involved tradeoffs between efficiency, size, and cost. Here more weight was given to efficiency than to size as evidenced by the low switching frequency which keeps switching losses low but pushes the value and size of the inductor up.

From a smaller circuit, use the component values shown in Figure 4 and those contained in Table 3. These circuits trade slightly higher switching losses for a much smaller inductor. Note, Figure 4 does not show R_{FA} , the resistor required to adjust the switching frequency from 90 kHz up to 200 kHz. Connect R_{FA} between the FREQ ADJ pin and ground.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

BANNED SUBSTANCE COMPLIANCE

National Semiconductor certifies that the products and packing materials meet the provisions of the Customer Products Stewardship Specification (CSP-9-111C2) and the Banned Substances and Materials of Interest Specification (CSP-9-111S2) and contain no "Banned Substances" as defined in CSP-9-111S2.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
