| 5.1 Block Diagram .....                                 | 88        |
| 5.2 Signal Description .....                            | 88        |
| 5.3 Functional Description .....                        | 89        |
| 5.3.1 JTAG Interface Pins .....                         | 89        |
| 5.3.2 JTAG TAP Controller .....                         | 91        |
| 5.3.3 Shift Registers .....                             | 91        |
| 5.3.4 Operational Considerations .....                  | 92        |
| 5.4 Initialization and Configuration .....              | 94        |

|          |                                                                 |            |
|----------|-----------------------------------------------------------------|------------|
| 5.5      | Register Descriptions .....                                     | 95         |
| 5.5.1    | Instruction Register (IR) .....                                 | 95         |
| 5.5.2    | Data Registers .....                                            | 97         |
| <b>6</b> | <b>System Control .....</b>                                     | <b>99</b>  |
| 6.1      | Signal Description .....                                        | 99         |
| 6.2      | Functional Description .....                                    | 99         |
| 6.2.1    | Device Identification .....                                     | 100        |
| 6.2.2    | Reset Control .....                                             | 100        |
| 6.2.3    | Non-Maskable Interrupt .....                                    | 104        |
| 6.2.4    | Power Control .....                                             | 105        |
| 6.2.5    | Clock Control .....                                             | 105        |
| 6.2.6    | System Control .....                                            | 112        |
| 6.3      | Initialization and Configuration .....                          | 113        |
| 6.4      | Register Map .....                                              | 114        |
| 6.5      | Register Descriptions .....                                     | 115        |
| <b>7</b> | <b>Internal Memory .....</b>                                    | <b>204</b> |
| 7.1      | Block Diagram .....                                             | 204        |
| 7.2      | Functional Description .....                                    | 204        |
| 7.2.1    | SRAM .....                                                      | 205        |
| 7.2.2    | ROM .....                                                       | 205        |
| 7.2.3    | Flash Memory .....                                              | 207        |
| 7.3      | Flash Memory Initialization and Configuration .....             | 208        |
| 7.3.1    | Flash Memory Programming .....                                  | 208        |
| 7.3.2    | 32-Word Flash Memory Write Buffer .....                         | 210        |
| 7.3.3    | Nonvolatile Register Programming .....                          | 210        |
| 7.4      | Register Map .....                                              | 211        |
| 7.5      | Flash Memory Register Descriptions (Flash Control Offset) ..... | 212        |
| 7.6      | Memory Register Descriptions (SystemDMA Control Offset) .....   | 223        |
| <b>8</b> | <b>Micro Direct Memory Access (μDMA) .....</b>                  | <b>241</b> |
| 8.1      | Block Diagram .....                                             | 242        |
| 8.2      | Functional Description .....                                    | 242        |
| 8.2.1    | Channel Assignments .....                                       | 243        |
| 8.2.2    | Priority .....                                                  | 244        |
| 8.2.3    | Arbitration Size .....                                          | 244        |
| 8.2.4    | Request Types .....                                             | 244        |
| 8.2.5    | Channel Configuration .....                                     | 245        |
| 8.2.6    | Transfer Modes .....                                            | 247        |
| 8.2.7    | Transfer Size and Increment .....                               | 255        |
| 8.2.8    | Peripheral Interface .....                                      | 255        |
| 8.2.9    | Software Request .....                                          | 255        |
| 8.2.10   | Interrupts and Errors .....                                     | 256        |
| 8.3      | Initialization and Configuration .....                          | 256        |
| 8.3.1    | Module Initialization .....                                     | 256        |
| 8.3.2    | Configuring a Memory-to-Memory Transfer .....                   | 256        |
| 8.3.3    | Configuring a Peripheral for Simple Transmit .....              | 258        |
| 8.3.4    | Configuring a Peripheral for Ping-Pong Receive .....            | 259        |
| 8.3.5    | Configuring Channel Assignments .....                           | 262        |
| 8.4      | Register Map .....                                              | 262        |

|           |                                                    |            |
|-----------|----------------------------------------------------|------------|
| 8.5       | μDMA Channel Control Structure .....               | 263        |
| 8.6       | μDMA Register Descriptions .....                   | 270        |
| <b>9</b>  | <b>General-Purpose Input/Outputs (GPIOs) .....</b> | <b>299</b> |
| 9.1       | Signal Description .....                           | 299        |
| 9.2       | Functional Description .....                       | 304        |
| 9.2.1     | Data Control .....                                 | 306        |
| 9.2.2     | Interrupt Control .....                            | 307        |
| 9.2.3     | Mode Control .....                                 | 308        |
| 9.2.4     | Commit Control .....                               | 308        |
| 9.2.5     | Pad Control .....                                  | 309        |

| June 2009 | 5779     | <ul style="list-style-type: none"> <li>■ In System Control chapter, clarified power-on reset and external reset pin descriptions in "Reset Sources" section.</li> <li>■ Added missing comparator output pin bits to <b>DC3</b> register; reset value changed as well.</li> <li>■ Clarified explanation of nonvolatile register programming in Internal Memory chapter.</li> <li>■ Added explanation of reset value to <b>FMPRE0/1/2/3</b>, <b>FMPPE0/1/2/3</b>, <b>USER_DBG</b>, and <b>USER_REG0</b> registers.</li> <li>■ In Request Type Support table in DMA chapter, corrected general-purpose timer row.</li> <li>■ In General-Purpose Timers chapter, clarified DMA operation.</li> <li>■ Added table "Preliminary Current Consumption" to Characteristics chapter.</li> <li>■ Corrected Nom and Max values in EPI Characteristics table.</li> <li>■ Added "CSn to output invalid" parameter to EPI table "EPI Host-Bus 8 and Host-Bus 16 Interface Characteristics" and figure "Host-Bus 8/16 Mode Read Timing".</li> <li>■ Corrected INL, DNL, OFF and GAIN values in ADC Characteristics table.</li> <li>■ Updated ROM DriverLib appendix with RevC0 functions.</li> <li>■ Updated part ordering numbers.</li> <li>■ Additional minor data sheet clarifications and corrections.</li> </ul> |
| May 2009  | 5285     | Started tracking revision history.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## About This Document

This data sheet provides reference information for the LM3S5791 microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M3 core.

### Audience

This manual is intended for system software developers, hardware designers, and application developers.

### About This Manual

This document is organized into sections that correspond to each major feature.

## Documentation Conventions

This document uses the conventions shown in Table 2 on page 42.

**Table 2. Documentation Conventions**

| Notation                              | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Register Notation</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>REGISTER</b>                       | APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .                                                                                                   |
| bit                                   | A single bit in a register.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| bit field                             | Two or more consecutive and related bits.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| offset 0xnnn                          | A hexadecimal increment to a register's address, relative to that module's base address as specified in "Memory Map" on page 81.                                                                                                                                                                                                                                                                                                                                      |
| Register N                            | Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.                                                                                                                                                                                                                                                                                                                              |
| reserved                              | Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                     |
| yy:xx                                 | The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.                                                                                                                                                                                                                                                                                                                                                     |
| <b>Register Bit/Field Types</b>       | This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.                                                                                                                                                                                                                                                                                                                                    |
| RC                                    | Software can read this field. The bit or field is cleared by hardware after reading the bit/field.                                                                                                                                                                                                                                                                                                                                                                    |
| RO                                    | Software can read this field. Always write the chip reset value.                                                                                                                                                                                                                                                                                                                                                                                                      |
| R/W                                   | Software can read or write this field.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| R/W1C                                 | Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged.<br><br>This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read. |
| R/W1S                                 | Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.                                                                                                                                                                                                                                                                                                                                            |
| W1C                                   | Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data.<br><br>This register is typically used to clear the corresponding bit in an interrupt register.                                                                                                         |
| WO                                    | Only a write by software is valid; a read of the register returns no meaningful data.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Register Bit/Field Reset Value</b> | This value in the register bit diagram shows the bit/field value after any reset, unless noted.                                                                                                                                                                                                                                                                                                                                                                       |
| 0                                     | Bit cleared to 0 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1                                     | Bit set to 1 on chip reset.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -                                     | Nondeterministic.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Pin/Signal Notation</b>            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| [ ]                                   | Pin alternate function; a pin defaults to the signal without the brackets.                                                                                                                                                                                                                                                                                                                                                                                            |
| pin                                   | Refers to the physical connection on the package.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| signal                                | Refers to the electrical signal encoding of a pin.                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 2. Documentation Conventions (continued)**

| Notation          | Meaning                                                                                                                                                                                                                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assert a signal   | Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and SIGNAL below).           |
| deassert a signal | Change the value of the signal from the logically True state to the logically False state.                                                                                                                                                                                                                                        |
| SIGNAL            | Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert SIGNAL is to drive it Low; to deassert SIGNAL is to drive it High.                                                                                                                                  |
| SIGNAL            | Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.                                                                                                                                                         |
| <b>Numbers</b>    |                                                                                                                                                                                                                                                                                                                                   |
| X                 | An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.                                                                                                                         |
| 0x                | Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF.<br><br>All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix. |

# 1 Architectural Overview

Texas Instruments is the industry leader in bringing 32-bit capabilities and the full benefits of ARM® Cortex-M3™-based microcontrollers to the broadest reach of the microcontroller market. For current users of 8- and 16-bit MCUs, Stellaris® with Cortex-M3 offers a direct path to the strongest ecosystem of development tools, software and knowledge in the industry. Designers who migrate to Stellaris® benefit from great tools, small code footprint and outstanding performance. Even more important, designers can enter the ARM ecosystem with full confidence in a compatible roadmap from \$1 to 1 GHz. For users of current 32-bit MCUs, the Stellaris® family offers the industry's first implementation of Cortex-M3 and the Thumb-2 instruction set. With blazingly-fast responsiveness, Thumb-2 technology combines both 16-bit and 32-bit instructions to deliver the best balance of code density and performance. Thumb-2 uses 26 percent less memory than pure 32-bit code to reduce system cost while delivering 25 percent better performance. The Texas Instruments Stellaris® family of microcontrollers—the first ARM® Cortex™-M3 based controllers—brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

The LM3S5791 microcontroller has the following features:

- ARM® Cortex™-M3 Processor Core
  - 80-MHz operation; 100 DMIPS performance
  - ARM Cortex SysTick Timer
  - Nested Vectored Interrupt Controller (NVIC)
- On-Chip Memory
  - 128 KB single-cycle Flash memory up to 50 MHz; a prefetch buffer improves performance above 50 MHz
  - 64 KB single-cycle SRAM
  - Internal ROM loaded with StellarisWare® software:
    - Stellaris® Peripheral Driver Library
    - Stellaris® Boot Loader
    - Advanced Encryption Standard (AES) cryptography tables
    - Cyclic Redundancy Check (CRC) error detection functionality
- External Peripheral Interface (EPI)
  - 8/16/32-bit dedicated parallel bus for external peripherals
  - Supports SDRAM, SRAM/Flash memory, FPGAs, CPLDs
- Advanced Serial Integration
  - Two CAN 2.0 A/B controllers

- USB 2.0 OTG/Host/Device
- Three UARTs with IrDA and ISO 7816 support (one UART with full modem controls)
- Two I<sup>2</sup>C modules
- Two Synchronous Serial Interface modules (SSI)
- Integrated Interchip Sound (I<sup>2</sup>S) module
- System Integration
  - Direct Memory Access Controller (DMA)
  - System control and clocks including on-chip precision 16-MHz oscillator
  - Four 32-bit timers (up to eight 16-bit)
  - Eight Capture Compare PWM pins (CCP)
  - Real-Time Clock
  - Two Watchdog Timers
    - One timer runs off the main oscillator
    - One timer runs off the precision internal oscillator
  - Up to 72 GPIOs, depending on configuration
    - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
    - Independently configurable to 2, 4 or 8 mA drive capability
    - Up to 4 GPIOs can have 18 mA drive capability
- Advanced Motion Control
  - Eight advanced PWM outputs for motion and energy applications
  - Four fault inputs to promote low-latency shutdown
  - Two Quadrature Encoder Inputs (QEI)
- Analog
  - Two 10-bit Analog-to-Digital Converters (ADC) with sixteen analog input channels and sample rate of one million samples/second
  - Three analog comparators
  - 16 digital comparators
  - On-chip voltage regulator
- JTAG and ARM Serial Wire Debug (SWD)

- 100-pin LQFP and 108-ball BGA package
- Industrial (-40°C to 85°C) Temperature Range

The Stellaris® LM3S5000 series, designed for Controller Area Network (CAN) applications, extends the Stellaris® family with Bosch CAN networking technology combined with USB 2.0 Full or Low Speed On-The-Go (OTG) or Host/Device capabilities. The LM3S5000 microcontrollers are perfect for cost-effective embedded control applications requiring industrial connectivity. The motion control features are suitable for fault conditioning and sophisticated motion control.

The LM3S5791 microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, motion control, medical instrumentation, and fire and security.

In addition, the LM3S5791 microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM3S5791 microcontroller is code-compatible to all members of the extensive Stellaris® family; providing flexibility to fit our customers' precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network. See "Ordering and Contact Information" on page 1211 for ordering information for Stellaris® family devices.

## 1.1 Functional Overview

The following sections provide an overview of the features of the LM3S5791 microcontroller. The page number in parentheses indicates where that feature is discussed in detail. Ordering and support information can be found in "Ordering and Contact Information" on page 1211.

### 1.1.1 ARM Cortex™-M3

The following sections provide an overview of the ARM Cortex™-M3 processor core and instruction set, the integrated System Timer (SysTick) and the Nested Vectored Interrupt Controller.

#### 1.1.1.1 Processor Core (see page 68)

All members of the Stellaris® product family, including the LM3S5791 microcontroller, are designed around an ARM Cortex™-M3 processor core. The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

- 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set, delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide

- Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
- Unaligned data access, enabling data to be efficiently packed into memory
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast multiplier
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage
- Ultra-low power consumption with integrated sleep modes
- 80-MHz operation
- 1.25 DMIPS/MHz

“ARM Cortex-M3 Processor Core” on page 68 provides an overview of the ARM core; the core is detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### 1.1.1.2 System Timer (SysTick) (see page 78)

ARM Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations. The COUNTFLAG field in the SysTick Control and Status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop

### 1.1.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 84)

The LM3S5791 controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M3 prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 52 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

“Interrupts” on page 84 provides an overview of the NVIC controller and the interrupt map. Exceptions and interrupts are detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

## 1.1.2 On-Chip Memory

The following sections describe the on-chip memory modules.

### 1.1.2.1 SRAM (see page 205)

The LM3S5791 microcontroller provides 64 KB of single-cycle on-chip SRAM. The internal SRAM of the Stellaris® devices is located at offset 0x2000.0000 of the device memory map.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the new Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from the SRAM using the Micro Direct Memory Access Controller (μDMA).

### 1.1.2.2 Flash Memory (see page 207)

The LM3S5791 microcontroller provides 128 KB of single-cycle on-chip Flash memory (above 50 MHz, the Flash memory can be accessed in a single cycle as long as the code is linear; branches incur a one-cycle stall). The Flash memory is organized as a set of 2-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 1.1.2.3 ROM (see page 205)

The LM3S5791 ROM is preprogrammed with the following software and programs:

- Stellaris® Peripheral Driver Library

- Stellaris® Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The Stellaris® Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM® Cortex™-M3 core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris® Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on lesser general public license (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

### 1.1.3 External Peripheral Interface (see page 356)

The External Peripheral Interface (EPI) provides access to external devices using a parallel path. Unlike communications peripherals such as SSI, UART, and I<sup>2</sup>C, the EPI is designed to act like a bus to external peripherals and memory.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal non-blocking read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

■ Synchronous Dynamic Random Access Memory (SDRAM)

- Supports x16 (single data rate) SDRAM at up to 50 MHz
- Supports low-cost SDRAMs up to 64 MB (512 megabits)
- Includes automatic refresh and access to all banks/rows
- Includes a Sleep/Standby mode to keep contents active with minimal power draw
- Multiplexed address/data interface for reduced pin count

■ Host-bus

- Traditional x8 and x16 MCU bus interface capabilities
- Similar device compatibility options as PIC, ATmega, 8051, and others
- Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in unmultiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)
- Support of both muxed and de-muxed address and data
- Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
- Speed controlled, with read and write data wait-state counters
- Chip select modes include ALE, CSn, Dual CSn and ALE with dual CSn
- Manual chip-enable (or use extra address pins)

■ General Purpose

- Wide parallel interfaces for fast communications with CPLDs and FPGAs
- Data widths up to 32-bits
- Data rates up to 150 MB/second
- Optional “address” sizes from 4 bits to 20 bits
- Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input

■ General parallel GPIO

- 1 to 32 bits, FIFOed with speed control
- Useful for custom peripherals or for digital data acquisition and actuator controls

### 1.1.4 Serial Communications Peripherals

The LM3S5791 controller supports both asynchronous and synchronous serial communications with:

- Two CAN 2.0 A/B Controllers
- USB 2.0 (full speed and low speed) OTG/Host/Device
- Three UARTs with IrDA and ISO 7816 support (one UART with full modem controls)
- Two I<sup>2</sup>C modules
- Two Synchronous Serial Interface modules (SSI)
- Integrated Interchip Sound (I<sup>2</sup>S) Module

The following sections provide more detail on each of these communications functions.

#### 1.1.4.1 Controller Area Network (see page 758)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The LM3S5791 microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

#### 1.1.4.2 USB (see page 810)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The LM3S5791 controller supports three configurations in USB 2.0 full and low speed: USB Device, USB Host, and USB On-The-Go (negotiated on-the-go as host or device when connected to other USB-enabled systems).

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation
- Integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 32 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 15 configurable IN endpoints and 15 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop and valid ID detection and interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

#### 1.1.4.3 UART (see page 580)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM3S5791 controller includes three fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem status, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The three UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity

- False-start bit detection
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Full modem handshake support (on UART1)
- LIN protocol support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

#### 1.1.4.4 I<sup>2</sup>C (see page 684)

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I<sup>2</sup>C bus can be designated as either a master or a slave. Each I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I<sup>2</sup>C master and slave can generate interrupts.

The LM3S5791 controller includes two I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave

- Supports both transmitting and receiving data as either a master or a slave
- Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

#### 1.1.4.5 SSI (see page 642)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface that converts data between parallel and serial. The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The LM3S5791 controller includes two SSI modules with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt

- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

#### 1.1.4.6 Inter-Integrated Circuit Sound (I<sup>2</sup>S) Interface (see page 721)

The I<sup>2</sup>S interface is a configurable serial audio core that contains a transmit module and a receive module. The module is configurable for the I<sup>2</sup>S as well as Left-Justified and Right-Justified serial audio formats. Data can be in one of four modes: Stereo, Mono, Compact 16-bit Stereo and Compact 8-Bit Stereo.

The transmit and receive modules each have an 8-entry audio-sample FIFO. An audio sample can consist of a Left and Right Stereo sample, a Mono sample, or a Left and Right Compact Stereo sample. In Compact 16-Bit Stereo, each FIFO entry contains both the 16-bit left and 16-bit right samples, allowing efficient data transfers and requiring less memory space. In Compact 8-bit Stereo, each FIFO entry contains an 8-bit left and an 8-bit right sample, reducing memory requirements further.

Both the transmitter and receiver are capable of being a master or a slave.

The Stellaris® I<sup>2</sup>S interface has the following features:

- Configurable audio format supporting I<sup>2</sup>S, Left-justification, and Right-justification
- Configurable sample size from 8 to 32 bits
- Mono and Stereo support
- 8-, 16-, and 32-bit FIFO interface for packing memory
- Independent transmit and receive 8-entry FIFOs
- Configurable FIFO-level interrupt and μDMA requests
- Independent transmit and receive MCLK direction control
- Transmit and receive internal MCLK sources
- Independent transmit and receive control for serial clock and word select
- MCLK and SCLK can be independently set to master or slave
- Configurable transmit zero or last sample when FIFO empty
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Burst requests
  - Channel requests asserted when FIFO contains required amount of data

### 1.1.5 System Integration

The LM3S5791 controller provides a variety of standard system functions integrated into the device, including:

- Micro Direct Memory Access Controller ( $\mu$ DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- ARM Cortex SysTick Timer
- Four 32-bit timers (up to eight 16-bit)
- Eight Capture Compare PWM pins (CCP)
- Real-Time Clock
- Two Watchdog Timers
- Up to 72 GPIOs, depending on configuration
  - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
  - Independently configurable to 2, 4 or 8 mA drive capability
  - Up to 4 GPIOs can have 18 mA drive capability

The following sections provide more detail on each of these functions.

#### 1.1.5.1 Direct Memory Access (see page 241)

The LM3S5791 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable  $\mu$ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules: GP Timer, USB, UART, ADC, EPI, SSI, I<sup>2</sup>S

- Primary and secondary channel assignments
- One channel each for receive and transmit path for bidirectional modules
- Dedicated channel for software-initiated transfers
- Per-channel configurable bus arbitration scheme
- Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

#### 1.1.5.2 System Control and Clocks (see page 99)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
  - On-chip fixed Low Drop-Out (LDO) voltage regulator
  - Low-power options for microcontroller: Sleep and Deep-sleep modes with clock gating
  - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
  - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock
  - Precision Oscillator (PIOSC): on-chip resource providing a 16 MHz  $\pm 1\%$  frequency at room temperature
    - 16 MHz  $\pm 3\%$  across temperature

- Software power down control for low power modes
- Main Oscillator (MOSC): a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.
  - External oscillator used with or without on-chip PLL: select supported frequencies from 1 MHz to 16.384 MHz.
  - External crystal: from DC to maximum device speed
- Internal 30-kHz Oscillator: on chip resource providing a 30 kHz  $\pm$  50% frequency, used during power-saving modes
- Flexible reset sources
  - Power-on reset (POR)
  - Reset pin assertion
  - Brown-out reset (BOR) detector alerts to system power drops
  - Software reset
  - Watchdog timer reset
  - MOSC failure

### 1.1.5.3 Four Programmable Timers (see page 429)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

The General-Purpose Timer Module (GPTM) contains four GPTM blocks with the following functional options:

- Count up or down
- 16- or 32-bit programmable one-shot timer
- 16- or 32-bit programmable periodic timer
- 16-bit general-purpose timer with an 8-bit prescaler
- 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
- Eight Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- ADC event trigger
- User-enabled stalling when the controller asserts CPU Halt flag during debug (excluding RTC mode)

- 16-bit input-edge count- or time-capture modes
- 16-bit PWM mode with software-programmable output inversion of the PWM signal
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

#### 1.1.5.4 CCP Pins (see page 437)

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The LM3S5791 microcontroller includes eight Capture Compare PWM pins (CCP) that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

#### 1.1.5.5 Watchdog Timers (see page 477)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The Stellaris® Watchdog Timer can generate an interrupt or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The LM3S5791 microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Stellaris® Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable

- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

#### 1.1.5.6 Programmable GPIOs (see page 299)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The Stellaris<sup>®</sup> GPIO module is comprised of nine physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-72 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 1066 for the signals available to each GPIO pin).

- Up to 72 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant input/outputs
- Fast toggle capable of a change every two clock cycles
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables

#### 1.1.6 Advanced Motion Control

The LM3S5791 controller provides motion control functions integrated into the device, including:

- Eight advanced PWM outputs for motion and energy applications
- Four fault input to promote low-latency shutdown

- Two Quadrature Encoder Inputs (QEI)

The following provides more detail on these motion control functions.

#### 1.1.6.1 PWM (see page 963)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control. The LM3S5791 PWM module consists of four PWM generator blocks and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted. PWM generator block has the following features:

- Four fault-condition handling input to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal

- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Synchronization of PWM output enables across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended fault capabilities with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

#### 1.1.6.2 QEI (see page 1041)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, the position, direction of rotation, and speed can be tracked. In addition, a third channel, or index signal, can be used to reset the position counter. The Stellaris<sup>®</sup> quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel. The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 20 MHz for a 80-MHz system).

The LM3S5791 microcontroller includes two QEI modules providing control of two motors at the same time with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

#### 1.1.7 Analog

The LM3S5791 controller provides analog functions integrated into the device, including:

- Two 10-bit Analog-to-Digital Converters (ADC) with sixteen analog input channels and sample rate of one million samples/second
- Three analog comparators

- 16 digital comparators
- On-chip voltage regulator

The following provides more detail on these analog functions.

#### 1.1.7.1 ADC (see page 502)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The Stellaris® ADC module features 10-bit conversion resolution and supports sixteen input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to eight analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. A digital comparator function is included that allows the conversion value to be diverted to a comparison unit that provides 16 digital comparators.

The LM3S5791 microcontroller provides two ADC modules with the following features:

- Sixteen analog input channels
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples for improved accuracy
- Digital comparison unit providing sixteen digital comparators
- Converter uses an internal 3-V reference or an external reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA

### 1.1.7.2 Analog Comparators (see page 949)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The LM3S5791 microcontroller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The LM3S5791 microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

### 1.1.8 JTAG and ARM Serial Wire Debug (see page 87)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system memory without halting the core or requiring any target resident code. See the *CoreSight™ Design Kit Technical Reference Manual* for details on SWJ-DP. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints

- Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
- Instrumentation Trace Macrocell (ITM) for support of printf style debugging
- Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

### **1.1.9 Packaging and Temperature**

- Industrial-range 100-pin RoHS-compliant LQFP package
- Industrial-range 108-ball RoHS-compliant BGA package

## **1.2 Target Applications**

The Stellaris® family is positioned for cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Remote monitoring
- Electronic point-of-sale (POS) machines
- Test and measurement equipment
- Network appliances and switches
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy
- Transportation

## **1.3 High-Level Block Diagram**

Figure 1-1 depicts the features on the Stellaris® LM3S5791 microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-1. Stellaris® LM3S5791 Microcontroller High-Level Block Diagram

## 1.4 Additional Features

### 1.4.1 Memory Map (see page 81)

A memory map lists the location of instructions and data in memory. The memory map for the LM3S5791 controller can be found in “Memory Map” on page 81. Register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. The *ARM® Cortex™-M3 Technical Reference Manual* provides further information on the memory map.

### 1.4.2 Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 1064
- “Signal Tables” on page 1066
- “Operating Characteristics” on page 1144
- “Electrical Characteristics” on page 1145
- “Package Information” on page 1213

## 2 ARM Cortex-M3 Processor Core

The ARM Cortex-M3 processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set, delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast multiplier
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage
- Ultra-low power consumption with integrated sleep modes
- 80-MHz operation
- 1.25 DMIPS/MHz

The Stellaris® family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motors.

For more information on the ARM Cortex-M3 processor core, see the *ARM® Cortex™-M3 Technical Reference Manual*. For information on SWJ-DP, see the *ARM® CoreSight Technical Reference Manual*.

## 2.1 Block Diagram

Figure 2-1. CPU Block Diagram

## 2.2 Functional Description

**Important:** The *ARM® Cortex™-M3 Technical Reference Manual* describes all the features of an ARM Cortex-M3 in detail. However, these features differ based on the implementation. This section describes the Stellaris® implementation.

Texas Instruments implements the ARM Cortex-M3 core as shown in Figure 2-1 on page 69. The Cortex-M3 uses the entire 16-bit Thumb instruction set and the base Thumb-2 32-bit instruction set. In addition, as noted in the *ARM® Cortex™-M3 Technical Reference Manual*, several Cortex-M3 components are flexible in their implementation: SW/JTAG-DP, ETM, TPIU, the ROM table, the MPU, and the Nested Vectored Interrupt Controller (NVIC). Each of these is addressed in the sections that follow.

### 2.2.1 Programming Model

This section provides a brief overview of the programming model for the Cortex-M3 core. More detailed information can be found in the *ARM® Cortex™-M3 Technical Reference Manual*.

- Privileged access and user access - Code can execute as privileged or unprivileged. Unprivileged execution limits or excludes access to some resources. Privileged execution has access to all resources. Handler mode is always privileged. Thread mode can be privileged or unprivileged.

Thread mode is privileged out of reset, but you can change it to user or unprivileged by setting the CONTROL[0] bit using the MSR instruction. User access prevents:

- Use of some instructions such as CPS to set FAULTMASK and PRIMASK
- Access to most registers in System Control Space (SCS)

When Thread mode has been changed from privileged to user, it cannot change itself back to privileged. Only a Handler can change the privilege of Thread mode. Handler mode is always privileged.

- Register set - The processor has the following 32-bit registers:
  - 13 general-purpose registers, r0-r12
  - Stack point alias of banked registers, SP\_process and SP\_main
  - Link register, r14
  - Program counter, r15
  - One program status register, xPSR.
- Data types - The processor supports the following data types:
  - 32-bit words
  - 16-bit halfwords
  - 8-bit bytes
- Memory formats - The processor views memory as a linear collection of bytes numbered in ascending order from 0. For example, bytes 0-3 hold the first stored word and bytes 4-7 hold the second stored word. The processor accesses code and data in little-endian format, which means that the byte with the lowest address in a word is the least-significant byte of the word. The byte with the highest address in a word is the most significant. The byte at address 0 of the memory system connects to data lines 7-0.
- Instruction set - The Cortex-M3 instruction set contains both 16 and 32-bit instructions. These instructions are summarized in Table 2-1 on page 70 and Table 2-2 on page 72, respectively.

**Table 2-1. 16-Bit Cortex-M3 Instruction Set Summary**

| Operation                                             | Assembler                    |
|-------------------------------------------------------|------------------------------|
| Add register value and C flag to register value       | ADC <Rd>, <Rm>               |
| Add immediate 3-bit value to register                 | ADD <Rd>, <Rn>, #<immed_3>   |
| Add immediate 8-bit value to register                 | ADD <Rd>, #<immed_8>         |
| Add low register value to low register value          | ADD <Rd>, <Rn>, <Rm>         |
| Add high register value to low or high register value | ADD <Rd>, <Rm>               |
| Add 4* (immediate 8-bit value) with PC to register    | ADD <Rd>, PC, #<immed_8> * 4 |
| Add 4* (immediate 8-bit value) with SP to register    | ADD <Rd>, SP, #<immed_8> * 4 |
| Add 4* (immediate 7-bit value) to SP                  | ADD SP, #<immed_7> * 4       |
| Bitwise AND register values                           | AND <Rd>, <Rm>               |
| Arithmetic shift right by immediate number            | ASR <Rd>, <Rm>, #<immed_5>   |

**Table 2-1. 16-Bit Cortex-M3 Instruction Set Summary (continued)**

| Operation                                                                  | Assembler                         |
|----------------------------------------------------------------------------|-----------------------------------|
| Arithmetic shift right by number in register                               | ASR <Rd>, <Rs>                    |
| Branch conditional                                                         | B<cond> <target address>          |
| Branch unconditional                                                       | B <target_address>                |
| Bit clear                                                                  | BIC <Rd>, <Rm>                    |
| Software breakpoint                                                        | BKPT <immed_8>                    |
| Branch with link                                                           | BL <Rm>                           |
| Branch with link and exchange                                              | BLX <Rm>                          |
| Branch and exchange                                                        | BX <Rm>                           |
| Compare not zero and branch                                                | CBNZ <Rn>, <label>                |
| Compare zero and branch                                                    | CBZ <Rn>, <label>                 |
| Compare negation of register value with another register value             | CMN <Rn>, <Rm>                    |
| Compare immediate 8-bit value                                              | CMP <Rn>, #<immed_8>              |
| Compare registers                                                          | CMP <Rn>, <Rm>                    |
| Compare high register to low or high register                              | CMP <Rn>, <Rm>                    |
| Change processor state                                                     | CPS <effect>, <iflags>            |
| Copy high or low register value to another high or low register            | CPY <Rd> <Rm>                     |
| Bitwise exclusive OR register values                                       | EOR <Rd>, <Rm>                    |
| Condition the following instruction                                        | IT <cond>                         |
| Condition the following two instructions                                   | IT<x> <cond>                      |
| Condition the following three instructions                                 | IT<x><y> <cond>                   |
| Condition the following four instructions                                  | IT<x><y><z> <cond>                |
| Multiple sequential memory word loads                                      | LDmia <Rn>!, <registers>          |
| Load memory word from base register address + 5-bit immediate offset       | LDR <Rd>, [<Rn>, #<immed_5> * 4]  |
| Load memory word from base register address + register offset              | LDR <Rd>, [<Rn>, <Rm>]            |
| Load memory word from PC address + 8-bit immediate offset                  | LDR <Rd>, [PC, #<immed_8> * 4]    |
| Load memory word from SP address + 8-bit immediate offset                  | LDR, <Rd>, [SP, #<immed_8> * 4]   |
| Load memory byte [7:0] from register address + 5-bit immediate offset      | LDRB <Rd>, [<Rn>, #<immed_5>]     |
| Load memory byte [7:0] from register address + register offset             | LDRB <Rd>, [<Rn>, <Rm>]           |
| Load memory halfword [15:0] from register address + 5-bit immediate offset | LDRH <Rd>, [<Rn>, #<immed_5> * 2] |
| Load halfword [15:0] from register address + register offset               | LDRH <Rd>, [<Rn>, <Rm>]           |
| Load signed byte [7:0] from register address + register offset             | LDRSB <Rd>, [<Rn>, <Rm>]          |
| Load signed halfword [15:0] from register address + register offset        | LDRSH <Rd>, [<Rn>, <Rm>]          |
| Logical shift left by immediate number                                     | LSL <Rd>, <Rm>, #<immed_5>        |
| Logical shift left by number in register                                   | LSL <Rd>, <Rs>                    |
| Logical shift right by immediate number                                    | LSR <Rd>, <Rm>, #<immed_5>        |
| Logical shift right by number in register                                  | LSR <Rd>, <Rs>                    |
| Move immediate 8-bit value to register                                     | MOV <Rd>, #<immed_8>              |
| Move low register value to low register                                    | MOV <Rd>, <Rn>                    |
| Move high or low register value to high or low register                    | MOV <Rd>, <Rm>                    |
| Multiply register values                                                   | MUL <Rd>, <Rm>                    |
| Move complement of register value to register                              | MVN <Rd>, <Rm>                    |
| Negate register value and store in register                                | NEG <Rd>, <Rm>                    |

Table 2-1. 16-Bit Cortex-M3 Instruction Set Summary (*continued*)

| Operation                                                                           | Assembler                         |
|-------------------------------------------------------------------------------------|-----------------------------------|
| No operation                                                                        | NOP <c>                           |
| Bitwise logical OR register values                                                  | ORR <Rd>, <Rm>                    |
| Pop registers from stack                                                            | POP <registers>                   |
| Pop registers and PC from stack                                                     | POP <registers, PC>               |
| Push registers onto stack                                                           | PUSH <registers>                  |
| Push LR and registers onto stack                                                    | PUSH <registers, LR>              |
| Reverse bytes in word and copy to register                                          | REV <Rd>, <Rn>                    |
| Reverse bytes in two halfwords and copy to register                                 | REV16 <Rd>, <Rn>                  |
| Reverse bytes in low halfword [15:0], sign-extend, and copy to register             | REVSH <Rd>, <Rn>                  |
| Rotate right by amount in register                                                  | ROR <Rd>, <Rs>                    |
| Subtract register value and C flag from register value                              | SBC <Rd>, <Rm>                    |
| Send event                                                                          | SEV <c>                           |
| Store multiple register words to sequential memory locations                        | STMIA <Rn>!, <registers>          |
| Store register word to register address + 5-bit immediate offset                    | STR <Rd>, [<Rn>, #<immed_5> * 4]  |
| Store register word to register address                                             | STR <Rd>, [<Rn>, <Rm>]            |
| Store register word to SP address + 8-bit immediate offset                          | STR <Rd>, [SP, #<immed_8> * 4]    |
| Store register byte [7:0] to register address + 5-bit immediate offset              | STRB <Rd>, [<Rn>, #<immed_5>]     |
| Store register byte [7:0] to register address                                       | STRB <Rd>, [<Rn>, <Rm>]           |
| Store register halfword [15:0] to register address + 5-bit immediate offset         | STRH <Rd>, [<Rn>, #<immed_5> * 2] |
| Store register halfword [15:0] to register address + register offset                | STRH <Rd>, [<Rn>, <Rm>]           |
| Subtract immediate 3-bit value from register                                        | SUB <Rd>, <Rn>, #<immed_3>        |
| Subtract immediate 8-bit value from register value                                  | SUB <Rd>, #<immed_8>              |
| Subtract register values                                                            | SUB <Rd>, <Rn>, <Rm>              |
| Subtract 4 (immediate 7-bit value) from SP                                          | SUB SP, #<immed_7> * 4            |
| Operating system service call with 8-bit immediate call code                        | SVC <immed_8>                     |
| Extract byte [7:0] from register, move to register, and sign-extend to 32 bits      | SXTB <Rd>, <Rm>                   |
| Extract halfword [15:0] from register, move to register, and sign-extend to 32 bits | SXTH <Rd>, <Rm>                   |
| Test register value for set bits by ANDing it with another register value           | TST <Rn>, <Rm>                    |
| Extract byte [7:0] from register, move to register, and zero-extend to 32 bits      | UXTB <Rd>, <Rm>10                 |
| Extract halfword [15:0] from register, move to register, and zero-extend to 32 bits | UXTH <Rd>, <Rm>                   |
| Wait for event                                                                      | WFE <c>                           |
| Wait for interrupt                                                                  | WFI <c>                           |

Table 2-2. 32-Bit Cortex-M3 Instruction Set Summary

| Operation                                              | Assembler                                        |
|--------------------------------------------------------|--------------------------------------------------|
| Add register value, immediate 12-bit value, and C bit  | ADC{S}.W <Rd>, <Rn>, #<modify_constant(immed_12> |
| Add register value, shifted register value, and C bit  | ADC{S}.W <Rd>, <Rn>, <Rm>{, <shift>}             |
| Add register value and immediate 12-bit value          | ADD{S}.W <Rd>, <Rn>, #<modify_constant(immed_12> |
| Add register value and shifted register value          | ADD{S}.W <Rd>, <Rm>{, <shift>}                   |
| Add register value and immediate 12-bit value          | ADDW.W <Rd>, <Rn>, #<immed_12>                   |
| Bitwise AND register value with immediate 12-bit value | AND{S}.W <Rd>, <Rn>, #<modify_constant(immed_12> |

**Table 2-2. 32-Bit Cortex-M3 Instruction Set Summary (continued)**

| Operation                                                                                                                     | Assembler                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Bitwise AND register value with shifted register value                                                                        | AND{S}.W <Rd>, <Rn>, Rm>{, <shift>}                                        |
| Arithmetic shift right by number in register                                                                                  | ASR{S}.W <Rd>, <Rn>, <Rm>                                                  |
| Conditional branch                                                                                                            | B{cond}.W <label>                                                          |
| Clear bit field                                                                                                               | BFC.W <Rd>, #<lsb>, #<width>                                               |
| Insert bit field from one register value into another                                                                         | BFI.W <Rd>, <Rn>, #<lsb>, #<width>                                         |
| Bitwise AND register value with complement of immediate 12-bit value                                                          | BIC{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>                          |
| Bitwise AND register value with complement of shifted register value                                                          | BIC{S}.W <Rd>, <Rn>, <Rm>{, <shift>}                                       |
| Branch with link                                                                                                              | BL <label>                                                                 |
| Branch with link (immediate)                                                                                                  | BL<c> <label>                                                              |
| Unconditional branch                                                                                                          | B.W <label>                                                                |
| Clear exclusive clears the local record of the executing processor that an address has had a request for an exclusive access. | CLREX <c>                                                                  |
| Return number of leading zeros in register value                                                                              | CLZ.W <Rd>, <Rn>                                                           |
| Compare register value with two's complement of immediate 12-bit value                                                        | CMN.W <Rn>, #<modify_constant(immed_12)>                                   |
| Compare register value with two's complement of shifted register value                                                        | CMN.W <Rn>, <Rm>{, <shift>}                                                |
| Compare register value with immediate 12-bit value                                                                            | CMP.W <Rn>, #<modify_constant(immed_12)>                                   |
| Compare register value with shifted register value                                                                            | CMP.W <Rn>, <Rm>{, <shift>}                                                |
| Data memory barrier                                                                                                           | DMB <c>                                                                    |
| Data synchronization barrier                                                                                                  | DSB <c>                                                                    |
| Exclusive OR register value with immediate 12-bit value                                                                       | EOR{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>                          |
| Exclusive OR register value with shifted register value                                                                       | EOR{S}.W <Rd>, <Rn>, <Rm>{, <shift>}                                       |

| Store doubleword, preindexed                                                                                                                                                                                            | STRD.W <Rxf>, <Rxf2>, [<Rn>, #+/-<offset_8> * 4]{!}                         |
| Store doubleword, postindexed                                                                                                                                                                                           | STRD.W <Rxf>, <Rxf2>, [<Rn>, #+/-<offset_8> * 4]                            |
| Store register exclusive calculates an address from a base register value and an immediate offset, and stores a word from a register to memory if the executing processor has exclusive access to the memory addressed. | STREX <c> <Rd>, <Rt>, [<Rn>{, #<imm>}]                                      |
| Store register exclusive byte derives an address from a base register value, and stores a byte from a register to memory if the executing processor has exclusive access to the memory addressed                        | STREXB <c> <Rd>, <Rt>, [<Rn>]                                               |
| Store register exclusive halfword derives an address from a base register value, and stores a halfword from a register to memory if the executing processor has exclusive access to the memory addressed.               | STREXH <c> <Rd>, <Rt>, [<Rn>]                                               |
| Register halfword [15:0] to register address + immediate 12-bit offset                                                                                                                                                  | STRH.W <Rxf>, [<Rn>, #<offset_12>]                                          |
| Register halfword [15:0] to register address shifted by 0, 1, 2, or 3 places                                                                                                                                            | STRH.W <Rxf>, [<Rn>, <Rm>{, LSL #<shift>}]                                  |
| Register halfword [15:0] to register address immediate 8-bit offset, preindexed                                                                                                                                         | STRH{T}.W <Rxf>, [<Rn>, #+/-<offset_8>]{!}                                  |

**Table 2-2. 32-Bit Cortex-M3 Instruction Set Summary (continued)**

| Operation                                                                        | Assembler                                         |
|----------------------------------------------------------------------------------|---------------------------------------------------|
| Register halfword [15:0] to register address immediate 8-bit offset, postindexed | STRH.W <Rxf>, [<Rn>], #+/-<offset_8>              |
| Subtract immediate 12-bit value from register value                              | SUB{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)> |
| Subtract shifted register value from register value                              | SUB{S}.W <Rd>, <Rn>, <Rm>{, <shift>}              |
| Subtract immediate 12-bit value from register value                              | SUBW.W <Rd>, <Rn>, #<immed_12>                    |
| Sign extend byte to 32 bits                                                      | SXTB.W <Rd>, <Rm>{, <rotation>}                   |
| Sign extend halfword to 32 bits                                                  | SXTH.W <Rd>, <Rm>{, <rotation>}                   |
| Table branch byte                                                                | TBB [<Rn>, <Rm>]                                  |
| Table branch halfword                                                            | TBH [<Rn>, <Rm>, LSL #1]                          |
| Exclusive OR register value with immediate 12-bit value                          | TEQ.W <Rn>, #<modify_constant(immed_12)>          |
| Exclusive OR register value with shifted register value                          | TEQ.W <Rn>, <Rm>{, <shift>}                       |
| Logical AND register value with 12-bit immediate value                           | TST.W <Rn>, #<modify_constant(immed_12)>          |
| Logical AND register value with shifted register value                           | TST.W <Rn>, <Rm>{, <shift>}                       |
| Copy bit field from register value to register and zero-extend to 32 bits        | UBFX.W <Rd>, <Rn>, #<lsb>, #<width>               |
| Unsigned divide                                                                  | UDIV<c> <Rd>, <Rn>, <Rm>                          |
| Multiply two unsigned register values and add to a 2-register value              | UMLAL.W <RdLo>, <RdHi>, <Rn>, <Rm>                |
| Multiply two unsigned register values                                            | UMULL.W <RdLo>, <RdHi>, <Rn>, <Rm>                |
| Unsigned saturate                                                                | USAT <c> <Rd>, #<imm>, <Rn>{, <shift>}            |
| Copy unsigned byte to register and zero-extend to 32 bits                        | UXTB.W <Rd>, <Rm>{, <rotation>}                   |
| Copy unsigned halfword to register and zero-extend to 32 bits                    | UXTH.W <Rd>, <Rm>{, <rotation>}                   |
| Wait for event                                                                   | WFE.W                                             |
| Wait for interrupt                                                               | WFI.W                                             |

## 2.2.2 Serial Wire and JTAG Debug

Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *CoreSight™ Design Kit Technical Reference Manual* for details on SWJ-DP.

## 2.2.3 Embedded Trace Macrocell (ETM)

ETM is not implemented in the Stellaris® devices. As a result, Chapters 15 and 16 of the *ARM® Cortex™-M3 Technical Reference Manual* can be ignored.

## 2.2.4 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M3 trace data from the ITM, and an off-chip Trace Port Analyzer. Stellaris® devices implement the TPIU as shown in Figure 2-2. This implementation is similar to the non-ETM version described in the *ARM® Cortex™-M3 Technical Reference Manual*, however, SWJ-DP only provides the Serial Wire Viewer (SWV) output format for the TPIU.

**Figure 2-2. TPIU Block Diagram**

### 2.2.5 ROM Table

The default ROM table is implemented as described in the *ARM® Cortex™-M3 Technical Reference Manual*.

### 2.2.6 Memory Protection Unit (MPU)

The Memory Protection Unit (MPU) is included on the LM3S5791 controller and supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

### 2.2.7 Nested Vectored Interrupt Controller (NVIC)

The Nested Vectored Interrupt Controller (NVIC):

- Facilitates low-latency exception and interrupt handling
- Controls power management
- Implements system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts. The NVIC maintains knowledge of the stacked (nested) interrupts to enable tail-chaining of interrupts.

You can only fully access the NVIC from privileged mode, but you can pend interrupts in user-mode by enabling the Configuration Control Register (see the *ARM® Cortex™-M3 Technical Reference Manual*). Any other user-mode access causes a bus fault.

All NVIC registers are accessible using byte, halfword, and word unless otherwise stated.

### 2.2.7.1 Interrupts

The ARM® Cortex™-M3 *Technical Reference Manual* describes the maximum number of interrupts and interrupt priorities. The LM3S5791 microcontroller supports 52 interrupts with eight priority levels.

In addition to the peripheral interrupts, the system also provides for a non-maskable interrupt (NMI). The NMI is generally used in safety critical applications where the immediate execution of an interrupt handler is required. The NMI signal is available as an external signal so that it may be generated by external circuitry. The NMI is also used internally as part of the main oscillator verification circuitry. More information on the non-maskable interrupt is located in “Non-Maskable Interrupt” on page 104.

### 2.2.8 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

#### 2.2.8.1 Functional Description

The timer consists of three registers:

- SysTick Control and Status Register - a control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status
- SysTick Reload Value Register - the reload value for the counter, used to provide the counter's wrap value
- SysTick Current Value Register - the current value of the counter

A fourth register, the SysTick Calibration Value Register, is not implemented in the Stellaris® devices.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the SysTick Reload Value register on the next clock edge, then decrements on subsequent clocks. Clearing the SysTick Reload Value register disables the counter on the next wrap. When the counter reaches zero, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

Writing to the SysTick Current Value register clears the register and the COUNTFLAG status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

If the core is in debug state (halted), the counter does not decrement. The timer is clocked with respect to a reference clock, which can be either the core clock or an external clock source.

### 2.2.8.2 SysTick Control and Status Register

Use the SysTick Control and Status Register to enable the SysTick features. The reset is 0x0000.0000.

| Bit/Field | Name      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|-----------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:17     | reserved  | RO   | 0x000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                            |
| 16        | COUNTFLAG | R/W  | 0     | Count Flag<br><br>When set, this bit indicates that the timer has counted to 0 since the last time this register was read.<br><br>This bit is cleared by a read of the register.<br><br>If read by the debugger using the DAP, this bit is cleared only if the MasterType bit in the AHB-AP Control Register is clear. Otherwise, the COUNTFLAG bit is not changed by the debugger read. |
| 15:3      | reserved  | RO   | 0x000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                            |
| 2         | CLKSOURCE | R/W  | 0     | Clock Source<br><br>Value Description<br>0 External reference clock. (Not implemented for Stellaris® microcontrollers.)<br>1 Core clock<br><br>Because an external reference clock is not supported, this bit must be set in order for SysTick to operate.                                                                                                                               |
| 1         | TICKINT   | R/W  | 0     | Tick Interrupt<br><br>When set, this bit causes an interrupt to be generated to the NVIC when SysTick counts to 0.<br><br>When clear, interrupt generation is disabled. Software can use the COUNTFLAG to determine if the counter has ever reached 0.                                                                                                                                   |
| 0         | ENABLE    | R/W  | 0     | Enable<br><br>When set, this bit enables SysTick to operate in a multi-shot way. That is, the counter loads the Reload value and begins counting down. On reaching 0, the COUNTFLAG bit is set and an interrupt is generated if enabled by TICKINT. The counter then loads the Reload value again and begins counting.<br><br>When this bit is clear, the counter is disabled.           |

### 2.2.8.3 SysTick Reload Value Register

The SysTick Reload Value Register specifies the start value to load into the SysTick Current Value Register when the counter reaches 0. The start value can be between 1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

When configuring SysTick as a single-shot timer, a new value is written on each tick interrupt, and the actual count down value must be written. For example, if a tick is next required after 400 clock pulses, 400 must be written into the RELOAD field.

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                   |
|-----------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24     | reserved | RO   | 0x00  | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 23:0      | RELOAD   | R/W  | -     | Reload Value<br>Value to load into the SysTick Current Value Register when the counter reaches 0.                                                                                             |

#### 2.2.8.4 SysTick Current Value Register

The SysTick Current Value Register contains the current value of the counter.

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                             |
|-----------|----------|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24     | reserved | RO   | 0x00  | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                           |
| 23:0      | CURRENT  | W1C  | -     | Current Value<br>This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care.<br>This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register. |

#### 2.2.8.5 SysTick Calibration Value Register

The SysTick Calibration Value register is not implemented.

### 3 Memory Map

The memory map for the LM3S5791 controller is provided in Table 3-1.

In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. See also Chapter 4, "Memory Map" in the *ARM® Cortex™-M3 Technical Reference Manual*.

Note that within the memory map, all reserved space returns a bus fault when read or written.

**Table 3-1. Memory Map**

| Start                   | End         | Description                                       | For details, see page ... |
|-------------------------|-------------|---------------------------------------------------|---------------------------|

## 4 Interrupts

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 4-1 on page 84 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 52 interrupts (listed in Table 4-2 on page 85).

Priorities on the system handlers are set with the NVIC System Handler Priority registers. Interrupts are enabled through the NVIC Interrupt Set Enable register and prioritized with the NVIC Interrupt Priority registers. Priorities can be grouped by splitting priority levels into pre-emption priorities and subpriorities. All of the interrupt registers are described in Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual*.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

If you assign the same priority level to two or more interrupts, their hardware priority (the lower position number) determines the order in which the processor activates them. For example, if both GPIO Port A and GPIO Port B are priority level 1, then GPIO Port A has higher priority.

**Important:** It may take several processor cycles after a write to clear an interrupt source for the NVIC to see the interrupt source de-assert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

See Chapter 5, “Exceptions” and Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual* for more information on exceptions and interrupts.

**Table 4-1. Exception Types**

| Exception Type               | Vector Number | Priority <sup>a</sup> | Description                                                                                                                                                                                                      |
|------------------------------|---------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -                            | 0             | -                     | Stack top is loaded from the first entry of the vector table on reset.                                                                                                                                           |
| Reset                        | 1             | -3 (highest)          | This exception is invoked on power up and warm reset. On the first instruction, Reset drops to the lowest priority (and then is called the base level of activation). This exception is asynchronous.            |
| Non-Maskable Interrupt (NMI) | 2             | -2                    | This exception is caused by the assertion of the NMI signal or by using the NVIC Interrupt Control State register and cannot be stopped or preempted by any exception but Reset. This exception is asynchronous. |
| Hard Fault                   | 3             | -1                    | This exception is caused by all classes of Fault, when the fault cannot activate due to priority or the configurable fault handler has been disabled. This exception is synchronous.                             |
| Memory Management            | 4             | programmable          | This exception is caused by an MPU mismatch, including access violation and no match. This exception is synchronous.                                                                                             |

**Table 4-1. Exception Types (continued)**

| Exception Type | Vector Number | Priority <sup>a</sup> | Description                                                                                                                                                                                                                              |
|----------------|---------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bus Fault      | 5             | programmable          | This exception is caused by a pre-fetch fault, memory access fault, and other address/memory related faults. This exception is synchronous when precise and asynchronous when imprecise.<br><br>This fault can be enabled or disabled.   |
| Usage Fault    | 6             | programmable          | This exception is caused by a usage fault, such as undefined instruction executed or illegal state transition attempt. This exception is synchronous.                                                                                    |
| -              | 7-10          | -                     | Reserved.                                                                                                                                                                                                                                |
| SVCall         | 11            | programmable          | This exception is caused by a system service call with an SVC instruction. This exception is synchronous.                                                                                                                                |
| Debug Monitor  | 12            | programmable          | This exception is caused by the debug monitor (when not halting). This exception is synchronous, but only active when enabled. This exception does not activate if it is a lower priority than the current activation.                   |
| -              | 13            | -                     | Reserved.                                                                                                                                                                                                                                |
| PendSV         | 14            | programmable          | This exception is caused by a pendable request for system service. This exception is asynchronous and only pending by software.                                                                                                          |
| SysTick        | 15            | programmable          | This exception is caused by the SysTick timer reaching 0, when it is enabled to generate an interrupt. This exception is asynchronous.                                                                                                   |
| Interrupts     | 16 and above  | programmable          | This exception is caused by interrupts asserted from outside the ARM Cortex-M3 core and fed through the NVIC (prioritized). These exceptions are all asynchronous. Table 4-2 on page 85 lists the interrupts on the LM3S5791 controller. |

a. 0 is the default priority for all the programmable priorities.

**Table 4-2. Interrupts**

| Vector Number | Interrupt Number (Bit in Interrupt Registers) | Description          |
|---------------|-----------------------------------------------|----------------------|
| 0-15          | -                                             | Processor exceptions |
| 16            | 0                                             | GPIO Port A          |
| 17            | 1                                             | GPIO Port B          |
| 18            | 2                                             | GPIO Port C          |
| 19            | 3                                             | GPIO Port D          |
| 20            | 4                                             | GPIO Port E          |
| 21            | 5                                             | UART0                |
| 22            | 6                                             | UART1                |

## 5 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Stellaris® JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Stellaris® JTAG instructions select the Stellaris® TDO output. The multiplexer is controlled by the Stellaris® JTAG controller, which has comprehensive programming for the ARM, Stellaris®, and unimplemented JTAG instructions.

The Stellaris® JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Cortex™-M3 Technical Reference Manual* for more information on the ARM JTAG controller.

## 5.1 Block Diagram

Figure 5-1. JTAG Module Block Diagram

## 5.2 Signal Description

Table 5-1 on page 88 and Table 5-2 on page 89 list the external signals of the JTAG/SWD controller and describe the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 308. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 324) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 342) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 299.

Table 5-1. Signals for JTAG\_SWO\_SWO (100LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| SWCLK    | 80         | PC0 (3)                  | I        | TTL                      | JTAG/SWD CLK.       |
| SWDIO    | 79         | PC1 (3)                  | I/O      | TTL                      | JTAG TMS and SWDIO. |
| SWO      | 77         | PC3 (3)                  | O        | TTL                      | JTAG TDO and SWO.   |
| TCK      | 80         | PC0 (3)                  | I        | TTL                      | JTAG/SWD CLK.       |
| TDI      | 78         | PC2 (3)                  | I        | TTL                      | JTAG TDI.           |
| TDO      | 77         | PC3 (3)                  | O        | TTL                      | JTAG TDO and SWO.   |

**Table 5-1. Signals for JTAG\_SWD\_SWO (100LQFP) (continued)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| TMS      | 79         | PC1 (3)                  | I        | TTL                      | JTAG TMS and SWDIO. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

**Table 5-2. Signals for JTAG\_SWD\_SWO (108BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description         |
|----------|------------|--------------------------|----------|--------------------------|---------------------|
| SWCLK    | A9         | PC0 (3)                  | I        | TTL                      | JTAG/SWD CLK.       |
| SWDIO    | B9         | PC1 (3)                  | I/O      | TTL                      | JTAG TMS and SWDIO. |
| SWO      | A10        | PC3 (3)                  | O        | TTL                      | JTAG TDO and SWO.   |
| TCK      | A9         | PC0 (3)                  | I        | TTL                      | JTAG/SWD CLK.       |
| TDI      | B8         | PC2 (3)                  | I        | TTL                      | JTAG TDI.           |
| TDO      | A10        | PC3 (3)                  | O        | TTL                      | JTAG TDO and SWO.   |
| TMS      | B9         | PC1 (3)                  | I        | TTL                      | JTAG TMS and SWDIO. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 5.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 5-1 on page 88. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 5-4 on page 95 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1150 for JTAG timing diagrams.

**Note:** Of all the possible reset sources, only Power-On reset (POR) and the assertion of the RST input have any effect on the JTAG module. The pin configurations are reset by both the RST input and POR, whereas the internal JTAG logic is only reset with POR. See “Reset Sources” on page 100 for more information on reset.

### 5.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated state after a power-on reset or reset caused by the RST input are given in Table 5-3. Detailed information on each pin follows. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 299 for information on how to reprogram the configuration of these pins.

**Table 5-3. JTAG Port Pins State after Power-On Reset or  $\overline{\text{RST}}$  assertion**

| Pin Name | Data Direction | Internal Pull-Up | Internal Pull-Down | Drive Strength | Drive Value |
|----------|----------------|------------------|--------------------|----------------|-------------|
| TCK      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TMS      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDI      | Input          | Enabled          | Disabled           | N/A            | N/A         |
| TDO      | Output         | Enabled          | Disabled           | 2-mA driver    | High-Z      |

#### 5.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 330 and page 332).

#### 5.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 5-2 on page 91.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 330).

#### 5.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 330).

#### 5.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the

chain being accessed. In order to save power when the JTAG port is not being used, the TD0 pin is placed in an inactive drive state when not actively shifting out data. Because TD0 can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TD0 to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TD0 pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 330 and page 332).

### 5.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 5-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

**Figure 5-2. Test Access Port State Machine**

### 5.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows

this information to be shifted out on TD0 during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TD0, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 95.

### 5.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

#### 5.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or RST, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (DEN[3:0] set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors (PUE[3:0] set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors (PDE[3:0] cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the alternate hardware function (AFSEL[3:0] set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 324, page 330, page 332, and page 335.

It is possible for software to configure these pins as GPIOs after reset by clearing AFSEL[3:0] in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

---

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

---

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

#### 5.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (TCK or SWCLK), the previous operation has enough time to complete and the ACK bits do not have to be checked.

### 5.3.4.3 Recovering a "Locked" Microcontroller

**Note:** Performing the sequence below restores the nonvolatile registers discussed in "Nonvolatile Register Programming" on page 210 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the nonvolatile registers being restored.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The sequence to recover the microcontroller is:

1. Assert and hold the RST signal.
2. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called "JTAG-to-SWD Switching" on page 94.
3. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called "SWD-to-JTAG Switching" on page 94.
4. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
5. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
6. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
7. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
8. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
9. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
10. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
11. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
12. Release the RST signal.
13. Wait 400 ms.
14. Power-cycle the microcontroller.

### 5.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M3 core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Cortex™-M3 Technical Reference Manual* and the *ARM® CoreSight Technical Reference Manual*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode, the SWD goes into the line reset state before sending the switch sequence.

### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode, the JTAG goes into the Test Logic Reset state before sending the switch sequence.

## **5.4 Initialization and Configuration**

After a Power-On-Reset or an external reset (RST), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins (PC[3:0]) should be returned to their default settings.

## 5.5 Register Descriptions

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

### 5.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TD0 pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 5-4. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 5-4. JTAG Instruction Register Commands**

| IR[3:0]    | Instruction      | Description                                                                                                                        |
|------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0x0        | EXTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.                          |
| 0x1        | INTEST           | Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.                    |
| 0x2        | SAMPLE / PRELOAD | Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in. |
| 0x8        | ABORT            | Shifts data into the ARM Debug Port Abort Register.                                                                                |
| 0xA        | DPACC            | Shifts data into and out of the ARM DP Access Register.                                                                            |
| 0xB        | APACC            | Shifts data into and out of the ARM AC Access Register.                                                                            |
| 0xE        | IDCODE           | Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.                |
| 0xF        | BYPASS           | Connects TDI to TD0 through a single Shift Register chain.                                                                         |
| All Others | Reserved         | Defaults to the BYPASS instruction to ensure that TDI is always connected to TD0.                                                  |

#### 5.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 5.5.1.2 INTEST Instruction

The INTEST instruction is not associated with its own Data Register chain. Instead, the INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. With tests that drive known values into the controller, this instruction can be used for testing. It is important to note that although the RST input pin is on the Boundary Scan Data Register chain, it is only observable.

While the INTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### **5.5.1.3 SAMPLE/PRELOAD Instruction**

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. See “Boundary Scan Data Register” on page 97 for more information.

#### **5.5.1.4 ABORT Instruction**

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 98 for more information.

#### **5.5.1.5 DPACC Instruction**

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 98 for more information.

#### **5.5.1.6 APACC Instruction**

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 98 for more information.

#### **5.5.1.7 IDCODE Instruction**

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 97 for more information.

### 5.5.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 97 for more information.

## 5.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

### 5.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M3 during debug.

**Figure 5-3. IDCODE Register Format**

### 5.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

**Figure 5-4. BYPASS Register Format**

### 5.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 5-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each

GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. The EXTEST instruction forces data out of the controller, and the INTEST instruction forces data into the controller.

**Figure 5-5. Boundary Scan Register Format**

#### 5.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### 5.5.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### 5.5.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

## 6 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

### 6.1 Signal Description

Table 6-1 on page 99 and Table 6-2 on page 99 list the external signals of the System Control module and describe the function of each. The NMI signal is the alternate function for the GPIO PB7 signal and functions as a GPIO after reset. PB7 is under commit protection and requires a special process to be configured as the NMI signal or to subsequently return to the GPIO function, see “Commit Control” on page 308. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the NMI signal. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 324) should be set to choose the NMI function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 342) to assign the NMI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 299. The remaining signals (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 6-1. Signals for System Control & Clocks (100LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| NMI      | 89         | PB7 (4)                  | I        | TTL                      | Non-maskable interrupt.                                                                   |
| OSC0     | 48         | fixed                    | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                       |
| OSC1     | 49         | fixed                    | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| RST      | 64         | fixed                    | I        | TTL                      | System reset input.                                                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

**Table 6-2. Signals for System Control & Clocks (108BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| NMI      | A8         | PB7 (4)                  | I        | TTL                      | Non-maskable interrupt.                                                                   |
| OSC0     | L11        | fixed                    | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                       |
| OSC1     | M11        | fixed                    | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| RST      | H11        | fixed                    | I        | TTL                      | System reset input.                                                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 6.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 100

- Local control, such as reset (see “Reset Control” on page 100), power (see “Power Control” on page 105) and clock control (see “Clock Control” on page 105)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 112

## 6.2.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, SRAM size, Flash memory size, and other features. See the **DID0** (page 116), **DID1** (page 144), **DC0-DC9** (page 146) and **NVMSTAT** (page 170) registers.

## 6.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

### 6.2.2.1 Reset Sources

The LM3S5791 microcontroller has six sources of reset:

1. Power-on reset (POR) (see page 101).
2. External reset input pin (RST) assertion (see page 101).
3. Internal brown-out (BOR) detector (see page 103).
4. Software-initiated reset (with the software reset registers) (see page 103).
5. A watchdog timer reset condition violation (see page 104).
6. MOSC failure (see page 104).

Table 6-3 provides a summary of results of the various reset operations.

**Table 6-3. Reset Sources**

| Reset Source                  | Core Reset?      | JTAG Reset?     | On-Chip Peripherals Reset? |
|-------------------------------|------------------|-----------------|----------------------------|
| Power-On Reset                | Yes              | Yes             | Yes                        |
| RST                           | Yes              | Pin Config Only | Yes                        |
| Brown-Out Reset               | Yes              | No              | Yes                        |
| Software System Request Reset | Yes <sup>a</sup> | No              | Yes                        |
| Software Peripheral Reset     | No               | No              | Yes <sup>b</sup>           |
| Watchdog Reset                | Yes              | No              | Yes                        |
| MOSC Failure Reset            | Yes              | No              | Yes                        |

a. By using the SYSRESETREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control register

b. Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, in which case, all the bits in the **RESC** register are cleared except for the POR indicator. A bit in the **RESC** register can be cleared by writing a 0.

At any reset that resets the core, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal in Ports A-H as configured

in the **Boot Configuration (BOOTCFG)** register. If the ROM boot loader is not selected, code in the ROM checks address 0x000.0004 to see if the Flash memory has a valid reset vector. If the data at address 0x0000.0004 is 0xFFFF.FFFF, then it is assumed that the Flash memory has not yet been programmed, and the core executes the ROM Boot Loader.

For example, if the **BOOTCFG** register is written and committed with the value of 0x0000.3C01, then PB7 is examined at reset to determine if the ROM boot loader should be executed. If PB7 is Low, the core unconditionally begins executing the ROM boot loader. If PB7 is High, then the application in Flash memory is executed if the reset vector at location 0x0000.0004 is not 0xFFFF.FFFF. Otherwise, the ROM boot loader is executed.

### 6.2.2.2 Power-On Reset (POR)

**Note:** The power-on reset also resets the JTAG controller. An external reset does not.

The internal Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{DD}$ ) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{TH}$ ). The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete. For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the RST input may be used as discussed in “External RST Pin” on page 101.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller. The Power-On Reset timing is shown in Figure 26-5 on page 1152.

### 6.2.2.3 External $\overline{\text{RST}}$ Pin

**Note:** It is recommended that the trace for the RST signal must be kept as short as possible. Be sure to place any components connected to the RST signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the RST input must be connected to the power supply ( $V_{DD}$ ) through an optional pull-up resistor (0 to 100K  $\Omega$ ) as shown in Figure 6-1 on page 101.

**Figure 6-1. Basic  $\overline{\text{RST}}$  Configuration**

$R_{PU} = 0 \text{ to } 100 \text{ k}\Omega$

The external reset pin (RST) resets the microcontroller including the core and all the on-chip peripherals except the JTAG TAP controller (see “JTAG Interface” on page 87). The external reset sequence is as follows:

1. The external reset pin (RST) is asserted for the duration specified by  $T_{\text{MIN}}$  and then de-asserted (see “Reset” on page 1151).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

To improve noise immunity and/or to delay reset at power up, the RST input may be connected to an RC network as shown in Figure 6-2 on page 102.

**Figure 6-2. External Circuitry to Extend Power-On Reset**

$R_{PU} = 1 \text{ k}\Omega$  to  $100 \text{ k}\Omega$

$C_1 = 1 \text{ nF}$  to  $10 \text{ }\mu\text{F}$

If the application requires the use of an external reset switch, Figure 6-3 on page 102 shows the proper circuitry to use.

**Figure 6-3. Reset Circuit Controlled by Switch**

Typical  $R_{PU} = 10 \text{ k}\Omega$

Typical  $R_S = 470 \text{ }\Omega$

$C_1 = 10 \text{ nF}$

The  $R_{PU}$  and  $C_1$  components define the power-on delay.

The external reset timing is shown in Figure 26-4 on page 1151.

#### 6.2.2.4 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the power supply ( $V_{DD}$ ) drops below a brown-out threshold voltage ( $V_{BTH}$ ). If a brown-out condition is detected, the system may generate an interrupt or a system reset. The default condition is to generate an interrupt, so BOR must be enabled. Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The BORIOR bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset; if BORIOR is clear, an interrupt is generated. When a Brown-out condition occurs during a Flash PROGRAM or ERASE operation, a full system reset is always triggered without regard to the setting in the **PBORCTL** register.

The brown-out reset sequence is as follows:

1. When  $V_{DD}$  drops below  $V_{BTH}$ , an internal BOR condition is set.
2. If the BOR condition exists, an internal reset is asserted.
3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.
4. The internal BOR condition is reset after 500  $\mu$ s to prevent another BOR condition from being set before software has a chance to investigate the original cause.

The result of a brown-out reset is equivalent to that of an assertion of the external RST input, and the reset is held active until the proper  $V_{DD}$  level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 26-6 on page 1152.

#### 6.2.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via three registers that control reset signals to each on-chip peripheral (see the **SRCRn** registers, page 197). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset. The encoding of the reset registers is consistent with the encoding of the clock gating control for peripherals and on-chip functions (see "System Control" on page 112).

The entire microcontroller including the core can be reset by software by setting the SYSRESETREQ bit in the Cortex-M3 Application Interrupt and Reset Control register. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the SYSRESETREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control register.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 26-7 on page 1152.

### 6.2.2.6 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The LM3S5791 microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). Each module operates in the same manner except that because the PIOSC watchdog timer module is in a different clock domain, register accesses must have a time delay between them. The watchdog timer can be configured to generate an interrupt to the microcontroller on its first time-out and to generate a reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the microcontroller. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see “Watchdog Timers” on page 477.

The watchdog reset timing is shown in Figure 26-8 on page 1152.

### 6.2.3 Non-Maskable Interrupt

The microcontroller has three sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal
- A main oscillator verification error
- The NMISSET bit in the **Interrupt Control and Status (ICSR)** register in the Cortex-M3.

Software must check the cause of the interrupt in order to distinguish among the sources.

#### 6.2.3.1 NMI Pin

The alternate function to GPIO port pin B7 is an NMI signal. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 299. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality, see page 338. The active sense of the NMI signal is High; asserting the enabled NMI signal above  $V_{IH}$  initiates the NMI interrupt sequence.

#### 6.2.3.2 Main Oscillator Verification Failure

The LM3S5791 microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. The main oscillator verification circuit can be programmed to generate a reset event, at which time a Power-on Reset is generated and control is transferred to the NMI handler. The NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the CVAL bit in the **Main Oscillator**

**Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Main Oscillator Verification Circuit” on page 112.

## 6.2.4 Power Control

The Stellaris® microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. For power reduction, a non-programmable LDO may be used to scale the microcontroller's 3.3 V input voltage to 1.2V. The voltage output has a minimum voltage of 1.08 V and a maximum of 1.35 V. The LDO delivers up to 60 ma.

Figure 6-4 shows the power architecture.

**Note:** On the printed circuit board, use the LDO output as the source of VDDC input. In addition, the LDO requires decoupling capacitors. See “On-Chip Low Drop-Out (LDO) Regulator Characteristics” on page 1146.

**Figure 6-4. Power Architecture**

## 6.2.5 Clock Control

System control determines the control of clocks in this part.

### 6.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller:

- **Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source that is the clock source the microcontroller uses during and following POR. It does not require the use of any external components and provides a clock that is 16 MHz  $\pm$  1% at room temperature and  $\pm$  3% across temperature. The PIOSC allows for a reduced system cost in applications that require an accurate clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference.
- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 3.579545 MHz through 16.384 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 1 MHz and 16.384 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller. The supported crystals are listed in the XTAL bit field in the **RCC** register (see page 127). Note that the MOSC must have a clock source for the USB PLL.
- **Internal 30-kHz Oscillator.** The internal 30-kHz oscillator provides an operational frequency of 30 kHz  $\pm$  50%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the MOSC and PIOSC to be powered down.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL and the precision internal oscillator divided by four (4 MHz  $\pm$  1%). The frequency of the PLL clock reference must be in the range of 3.579545 MHz to 16.384 MHz (inclusive). Table 6-4 on page 106 shows how the various clock sources can be used in a system.

**Table 6-4. Clock Source Options**

| Clock Source                                               | Drive PLL? |                          | Used as SysClk? |                          |
|------------------------------------------------------------|------------|--------------------------|-----------------|--------------------------|
| Precision Internal Oscillator                              | Yes        | BYPASS = 0, OSCSRC = 0x1 | Yes             | BYPASS = 1, OSCSRC = 0x1 |
| Precision Internal Oscillator divide by 4 (4 MHz $\pm$ 1%) | No         | BYPASS = 1               | Yes             | BYPASS = 1, OSCSRC = 0x2 |
| Main Oscillator                                            | Yes        | BYPASS = 0, OSCSRC = 0x0 | Yes             | BYPASS = 1, OSCSRC = 0x0 |
| Internal 30-kHz Oscillator                                 | No         | BYPASS = 1               | Yes             | BYPASS = 1, OSCSRC = 0x3 |

### 6.2.5.2 Clock Configuration

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options. These registers control the following clock functionality:

- Source of clocks in sleep and deep-sleep modes

- System clock derived from PLL or other clock source
- Enabling/disabling of oscillators and PLL
- Clock divisors
- Crystal input selection

Figure 6-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal is automatically divided down to 16 MHz for proper ADC operation. The PWM clock signal is a synchronous divide of the system clock to provide the PWM circuit with more range (set with PWM DIV in **RCC**).

**Note:** When the ADC module is in operation, the system clock must be at least 16 MHz.

Figure 6-5. Main Clock Tree

- a. Control provided by **RCC** register bit/field.  
 b. Control provided by **RCC** register bit/field or **RCC2** register bit/field, if overridden with **RCC2** register bit **USERCC2**.  
 c. Control provided by **RCC2** register bit/field.  
 d. Also may be controlled by **DSLPCCLKCFG** when in deep sleep mode.  
 e. Control provided by **RCC** register **SYSDIV** field, **RCC2** register **SYSDIV2** field if overridden with **USERCC2** bit, or **[SYSDIV2,SYSDIV2LSB]** if both **USERCC2** and **DIV400** bits are set.

**Note:** The figure above shows all features available on all Stellaris® Tempest-class microcontrollers.

In the **RCC** register, the **SYSDIV** field specifies which divisor is used to generate the system clock from either the PLL output or the oscillator source (depending on how the **BYPASS** bit in this register is configured). When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. Table 6-5 shows how the **SYSDIV** encoding affects the system clock frequency, depending on whether the PLL is used (**BYPASS**=0) or another clock source is used (**BYPASS**=1). The divisor is equivalent to the **SYSDIV** encoding plus 1. For a list of possible clock sources, see Table 6-4 on page 106.

**Table 6-5. Possible System Clock Frequencies Using the SYSDIV Field**

| SYSDIV | Divisor | Frequency (BYPASS=0) | Frequency (BYPASS=1)      | StellarisWare Parameter <sup>a</sup> |
|--------|---------|----------------------|---------------------------|--------------------------------------|
| 0x0    | /1      | reserved             | Clock source frequency/2  | SYSCTL_SYSDIV_1 <sup>b</sup>         |
| 0x1    | /2      | reserved             | Clock source frequency/2  | SYSCTL_SYSDIV_2                      |
| 0x2    | /3      | 66.67 MHz            | Clock source frequency/3  | SYSCTL_SYSDIV_3                      |
| 0x3    | /4      | 50 MHz               | Clock source frequency/4  | SYSCTL_SYSDIV_4                      |
| 0x4    | /5      | 40 MHz               | Clock source frequency/5  | SYSCTL_SYSDIV_5                      |
| 0x5    | /6      | 33.33 MHz            | Clock source frequency/6  | SYSCTL_SYSDIV_6                      |
| 0x6    | /7      | 28.57 MHz            | Clock source frequency/7  | SYSCTL_SYSDIV_7                      |
| 0x7    | /8      | 25 MHz               | Clock source frequency/8  | SYSCTL_SYSDIV_8                      |
| 0x8    | /9      | 22.22 MHz            | Clock source frequency/9  | SYSCTL_SYSDIV_9                      |
| 0x9    | /10     | 20 MHz               | Clock source frequency/10 | SYSCTL_SYSDIV_10                     |
| 0xA    | /11     | 18.18 MHz            | Clock source frequency/11 | SYSCTL_SYSDIV_11                     |
| 0xB    | /12     | 16.67 MHz            | Clock source frequency/12 | SYSCTL_SYSDIV_12                     |
| 0xC    | /13     | 15.38 MHz            | Clock source frequency/13 | SYSCTL_SYSDIV_13                     |
| 0xD    | /14     | 14.29 MHz            | Clock source frequency/14 | SYSCTL_SYSDIV_14                     |
| 0xE    | /15     | 13.33 MHz            | Clock source frequency/15 | SYSCTL_SYSDIV_15                     |
| 0xF    | /16     | 12.5 MHz (default)   | Clock source frequency/16 | SYSCTL_SYSDIV_16                     |

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

The SYSDIV2 field in the **RCC2** register is 2 bits wider than the SYSDIV field in the **RCC** register so that additional larger divisors up to /64 are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. When using the PLL, the VCO frequency of 400 MHz is predivided by 2 before the divisor is applied. The divisor is equivalent to the SYSDIV2 encoding plus 1. Table 6-6 shows how the SYSDIV2 encoding affects the system clock frequency, depending on whether the PLL is used (BYPASS2=0) or another clock source is used (BYPASS2=1). For a list of possible clock sources, see Table 6-4 on page 106.

**Table 6-6. Examples of Possible System Clock Frequencies Using the SYSDIV2 Field**

| SYSDIV2 | Divisor | Frequency (BYPASS2=0) | Frequency (BYPASS2=1)     | StellarisWare Parameter <sup>a</sup> |
|---------|---------|-----------------------|---------------------------|--------------------------------------|
| 0x00    | /1      | reserved              | Clock source frequency/2  | SYSCTL_SYSDIV_1 <sup>b</sup>         |
| 0x01    | /2      | reserved              | Clock source frequency/2  | SYSCTL_SYSDIV_2                      |
| 0x02    | /3      | 66.67 MHz             | Clock source frequency/3  | SYSCTL_SYSDIV_3                      |
| 0x03    | /4      | 50 MHz                | Clock source frequency/4  | SYSCTL_SYSDIV_4                      |
| ...     | ...     | ...                   | ...                       | ...                                  |
| 0x09    | /10     | 20 MHz                | Clock source frequency/10 | SYSCTL_SYSDIV_10                     |
| ...     | ...     | ...                   | ...                       | ...                                  |
| 0x3F    | /64     | 3.125 MHz             | Clock source frequency/64 | SYSCTL_SYSDIV_64                     |

a. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

b. SYSCTL\_SYSDIV\_1 does not set the USESYSDIV bit. As a result, using this parameter without enabling the PLL results in the system clock having the same frequency as the clock source.

To allow for additional frequency choices when using the PLL, the DIV400 bit is provided along with the SYSDIV2LSB bit. When the DIV400 bit is set, bit 22 becomes the LSB for SYSDIV2. In

this situation, the divisor is equivalent to the (SYSDIV2 encoding with SYSDIV2LSB appended) plus one. Table 6-7 shows the frequency choices when DIV400 is set. When the DIV400 bit is clear, SYSDIV2LSB is ignored, and the system clock frequency is determined as shown in Table 6-6 on page 109.

**Table 6-7. Examples of Possible System Clock Frequencies with DIV400=1**

| SYSDIV2 | SYSDIV2LSB | Divisor | Frequency (BYPASS2=0) <sup>a</sup> | StellarisWare Parameter <sup>b</sup> |
|---------|------------|---------|------------------------------------|--------------------------------------|
| 0x00    | reserved   | /2      | reserved                           | -                                    |
| 0x01    | 0          | /3      | reserved                           | -                                    |
|         | 1          | /4      | reserved                           | -                                    |
| 0x02    | 0          | /5      | 80 MHz                             | SYSCTL_SYSDIV_2_5                    |

|         | 1          | /128    | 3.125 MHz                          | SYSCTL_SYSDIV_64                     |

a. Note that DIV400 and SYSDIV2LSB are only valid when BYPASS2=0.

b. This parameter is used in functions such as SysCtlClockSet() in the Stellaris Peripheral Driver Library.

### 6.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC can be powered down by setting the IOSCDIS bit in the **RCC** register.

The PIOSC generates a 16 MHz clock with a  $\pm 1\%$  accuracy at room temperatures. Across the extended temperature range, the accuracy is  $\pm 3\%$ . At the factory, the PIOSC is set to 16 MHz at room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in one of two ways:

- Default calibration: clear the UTEN bit and set the UPDATE bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- User-defined calibration: The user can program the UT value to adjust the PIOSC frequency. As the UT value increases, the generated period increases. To commit a new UT value, first set the UTEN bit, then program the UT field, and then set the UPDATE bit. The adjustment finishes within a few clock periods and is glitch free.

### 6.2.5.4 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals. If the main oscillator is used by the PLL as a reference clock, the supported range of crystals is 3.579545 to 16.384 MHz, otherwise, the range of supported crystals is 1 to 16.384 MHz.

The XTAL bit in the **RCC** register (see page 127) describes the available crystal choices and default programming values.

Software configures the **RCC** register XTAL field with the crystal number. If the PLL is used in the design, the XTAL field value is internally translated to the PLL settings.

### 6.2.5.5 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the main PLL to drive the output. The PLL operates at 400 MHz, but is divided by two prior to the application of the output divisor.

To configure the PIOSC to be the clock source for the main PLL, program the OSCRC2 field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x1.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **XTAL to PLL Translation (PLLCFG)** register (see page 132). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 26-9 on page 1148 shows the actual PLL frequency and error for a given crystal choice.

The Crystal Value field (XTAL) in the **Run-Mode Clock Configuration (RCC)** register (see page 127) describes the available crystal choices and default programming of the **PLLCFG** register. Any time the XTAL field changes, the new settings are translated and the internal PLL settings are updated.

### 6.2.5.6 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the USBPWRDN bit of the **RCC2** register. The XTAL bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 4, 5, 6, 8, 10, 12, or 16 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

### 6.2.5.7 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 127 and page 135).

### 6.2.5.8 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{\text{READY}}$  (see Table 26-8 on page 1148). During the relock time, the affected PLL is not usable as a clock reference.

Either PLL is changed by one of the following:

- Change to the XTAL value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter is defined to measure the  $T_{\text{READY}}$  requirement. The counter is clocked by the main oscillator. The range of the main oscillator has been taken into account and the down counter is set to 0x1200 (that is, ~600  $\mu\text{s}$  at an 8.192 MHz external oscillator clock). When the XTAL value is greater than 0x0F, the down counter is set to 0x2400 to maintain the required lock time on higher frequency crystal inputs. Hardware is provided to keep the PLL from being used as a system clock

until the  $T_{\text{READY}}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the microcontroller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable ( $T_{\text{READY}}$  time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the PLLLRIS bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time ( $T_{\text{READY}}$ ), and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the  $T_{\text{READY}}$  period has passed, including periodically polling the USBPLLLRIS bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

#### 6.2.5.9 Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, the following sequence is performed by the hardware:

1. The MOSCFAIL bit in the **Reset Cause (RESC)** register is set.
2. If the internal oscillator (PIOSC) is disabled, it is enabled.
3. The system clock is switched from the main oscillator to the PIOSC.
4. An internal power-on reset is initiated that lasts for 32 PIOSC periods.
5. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

#### 6.2.6 System Control

For power-savings purposes, the **RCGCn**, **SCGCn**, and **DCGCn** registers control the clock gating logic for each peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. The **DC1**, **DC2** and **DC4** registers act as a write mask for the **RCGCn**, **SCGCn**, and **DCGCn** registers.

There are three levels of operation for the microcontroller defined as:

- **Run Mode.** In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the **RCGCn** registers. The system clock can be any of the available clock sources including the PLL.
- **Sleep Mode.** In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M3 core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

Peripherals are clocked that are enabled in the **SCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

- **Deep-Sleep Mode.** In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first writing the Deep Sleep Enable bit in the ARM Cortex-M3 NVIC system control register and then executing a WFI instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

The Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **DCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when auto-clock gating is disabled. The system clock source is specified in the **DSLPCLKCFG** register. When the **DSLPCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the WFI instruction, hardware powers the PLL down and overrides the SYSDIV field of the active **RCC/RCC2** register, to be determined by the DSDIVORIDE setting in the **DSLPCLKCFG** register, up to /16 or /64 respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 139.

**Caution – If the Cortex-M3 Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.**

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a WFI (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

## 6.3 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the USERCC2 bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the BYPASS bit and clearing the USESYS bit in the **RCC** register, thereby configuring the microcontroller to run off a “raw” clock source and allowing for the new PLL configuration to be validated before switching the system clock to the PLL.
2. Select the crystal value (XTAL) and oscillator source (OSCSRC), and clear the PWRDN bit in **RCC/RCC2**. Setting the XTAL field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the PWRDN bit powers and enables the PLL and its output.

3. Select the desired system divider (SYSDIV) in **RCC/RCC2** and set the USESYS bit in **RCC**. The SYSDIV field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the PLLLRIS bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the BYPASS bit in **RCC/RCC2**.

## 6.4 Register Map

Table 6-8 on page 114 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the "Internal Memory" on page 204.

**Table 6-8. System Control Register Map**

| Offset | Name    | Type  | Reset       | Description                        | See page |

## 6.5 Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000.

## Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the microcontroller.

### Device Identification 0 (DID0)

Base 0x400F.E000

Offset 0x000

Type RO, reset -

### Register 3: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

## Register 4: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

## Register 5: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are R/W1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 119).

### Masked Interrupt Status and Clear (MISC)

|   |            |       |   |                                       |
|---|------------|-------|---|---------------------------------------|
| 8 | MOSCPUPMIS | R/W1C | 0 | MOSC Power Up Masked Interrupt Status |
|---|------------|-------|---|---------------------------------------|

#### Value Description

1 When read, a 1 indicates that an unmasked interrupt was signaled because sufficient time has passed for the MOSC PLL to lock.

Writing a 1 to this bit clears it and also the MOSCPUPRIS bit in the **RIS** register.

0 When read, a 0 indicates that sufficient time has not passed for the MOSC PLL to lock.

A write of 0 has no effect on the state of this bit.

|---|------------|-------|---|--------------------------------------|

#### Value Description

1 When read, a 1 indicates that an unmasked interrupt was signaled because sufficient time has passed for the USB PLL to lock.

Writing a 1 to this bit clears it and also the USBPLLRRIS bit in the **RIS** register.

0 When read, a 0 indicates that sufficient time has not passed for the USB PLL to lock.

A write of 0 has no effect on the state of this bit.

## Register 6: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an power-on reset is the cause, in which case, all bits other than POR in the **RESC** register are cleared.

### Reset Cause (RESC)

The encoding for this field is provided below. Depending on the crystal used, the PLL frequency may not be exactly 400 MHz, see Table 26-9 on page 1148 for more information.</p> <p>Frequencies that may be used with the USB interface are indicated in the table. To function within the clocking requirements of the USB specification, a crystal of 4, 5, 6, 8, 10, 12, or 16 MHz must be used.</p> <table><tr><th>Value</th><th>Crystal Frequency (MHz) Not Using the PLL</th><th>Crystal Frequency (MHz) Using the PLL</th></tr><tr><td>0x00</td><td>1.000</td><td>reserved</td></tr><tr><td>0x01</td><td>1.8432</td><td>reserved</td></tr><tr><td>0x02</td><td>2.000</td><td>reserved</td></tr><tr><td>0x03</td><td>2.4576</td><td>reserved</td></tr><tr><td>0x04</td><td></td><td>3.579545 MHz</td></tr><tr><td>0x05</td><td></td><td>3.6864 MHz</td></tr><tr><td>0x06</td><td></td><td>4 MHz (USB)</td></tr><tr><td>0x07</td><td></td><td>4.096 MHz</td></tr><tr><td>0x08</td><td></td><td>4.9152 MHz</td></tr><tr><td>0x09</td><td></td><td>5 MHz (USB)</td></tr><tr><td>0x0A</td><td></td><td>5.12 MHz</td></tr><tr><td>0x0B</td><td></td><td>6 MHz (reset value)(USB)</td></tr><tr><td>0x0C</td><td></td><td>6.144 MHz</td></tr><tr><td>0x0D</td><td></td><td>7.3728 MHz</td></tr><tr><td>0x0E</td><td></td><td>8 MHz (USB)</td></tr><tr><td>0x0F</td><td></td><td>8.192 MHz</td></tr><tr><td>0x10</td><td></td><td>10.0 MHz (USB)</td></tr><tr><td>0x11</td><td></td><td>12.0 MHz (USB)</td></tr><tr><td>0x12</td><td></td><td>12.288 MHz</td></tr><tr><td>0x13</td><td></td><td>13.56 MHz</td></tr><tr><td>0x14</td><td></td><td>14.31818 MHz</td></tr><tr><td>0x15</td><td></td><td>16.0 MHz (USB)</td></tr><tr><td>0x16</td><td></td><td>16.384 MHz</td></tr></table> | Value | Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL | 0x00 | 1.000 | reserved | 0x01 | 1.8432 | reserved | 0x02 | 2.000 | reserved | 0x03 | 2.4576 | reserved | 0x04 |  | 3.579545 MHz | 0x05 |  | 3.6864 MHz | 0x06 |  | 4 MHz (USB) | 0x07 |  | 4.096 MHz | 0x08 |  | 4.9152 MHz | 0x09 |  | 5 MHz (USB) | 0x0A |  | 5.12 MHz | 0x0B |  | 6 MHz (reset value)(USB) | 0x0C |  | 6.144 MHz | 0x0D |  | 7.3728 MHz | 0x0E |  | 8 MHz (USB) | 0x0F |  | 8.192 MHz | 0x10 |  | 10.0 MHz (USB) | 0x11 |  | 12.0 MHz (USB) | 0x12 |  | 12.288 MHz | 0x13 |  | 13.56 MHz | 0x14 |  | 14.31818 MHz | 0x15 |  | 16.0 MHz (USB) | 0x16 |  | 16.384 MHz |

## Register 8: XTAL to PLL Translation (PLLCFG), offset 0x064

This register provides a means of translating external crystal frequencies into the appropriate PLL settings. This register is initialized during the reset sequence and updated anytime that the XTAL field changes in the **Run-Mode Clock Configuration (RCC)** register (see page 127).

The PLL frequency is calculated using the **PLLCFG** field values, as follows:

$$PLLFreq = OSCFreq * F / (R + 1)$$

**Register 9: GPIO High-Performance Bus Control (GPIOHBCTL), offset 0x06C**

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced High-Performance Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 9-7 on page 312).

## Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields, as shown in Table 6-9, when the **USERCC2** bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. Each **RCC2** field that supersedes an **RCC** field is located at the same LSB bit position; however, some **RCC2** fields are larger than the corresponding **RCC** field.

**Table 6-9. RCC2 Fields that Override RCC fields**

| RCC2 Field...        | Overrides RCC Field |
|----------------------|---------------------|
| SYSDIV2, bits[28:23] | SYSDIV, bits[26:23] |
| PWRDN2, bit[13]      | PWRDN, bit[13]      |
| BYPASS2, bit[11]     | BYPASS, bit[11]     |
| OSCSRC2, bits[6:4]   | OSCSRC, bits[5:4]   |

## Register 11: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides the ability to enable the MOSC clock verification circuit. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler.

### Main Oscillator Control (MOSCCTL)

## Register 13: Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150

This register provides the ability to update or recalibrate the precision internal oscillator.

### Precision Internal Oscillator Calibration (PIOSCCAL)

Base 0x400F.E000

## Register 14: I<sup>2</sup>S MCLK Configuration (I2SMCLKCFG), offset 0x170

This register configures the receive and transmit fractional clock dividers for the for the I<sup>2</sup>S master transmit and receive clocks (I2S0TXMCLK and I2S0RXMCLK) . Varying the integer and fractional inputs for the clocks allows greater accuracy in hitting the target I<sup>2</sup>S clock frequencies. Refer to “Clock Control” on page 726 for combinations of the TXI and TXF bits and the RXI and RXF bits that provide MCLK frequencies within acceptable error limits.

## Register 15: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, and package type.

### Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset -

## Register 17: Device Capabilities 1 (DC1), offset 0x010

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the RCGC0, SCGC0, and DCGC0 registers cannot be set.

## Register 18: Device Capabilities 2 (DC2), offset 0x014

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the RCGC0, SCGC0, and DCGC0 registers cannot be set.

### Device Capabilities 2 (DC2)

Base 0x400F.E000

## Register 19: Device Capabilities 3 (DC3), offset 0x018

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the RCGC0, SCGC0, and DCGC0 registers cannot be set.

### Device Capabilities 3 (DC3)

Base 0x400F.E000

Offset 0x018

Type RO, reset 0xBFFF.FFFF

## Register 23: Device Capabilities 7 (DC7), offset 0x028

This register is predefined by the part and can be used to verify uDMA channel features. A 1 indicates the channel is available on this device; a 0 that the channel is only available on other devices in the family. Most channels have primary and secondary assignments. If the primary function is not available on this microcontroller, the secondary function becomes the primary function. If the secondary function is not available, the primary function is the only option.

## Register 27: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 28: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 29: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 30: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 31: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

### Sleep Mode Clock Gating Control Register 1 (SCGC1)

Base 0x400F.E000

## Register 32: Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

**Register 33: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108**

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 34: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 35: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## 7 Internal Memory

The LM3S5791 microcontroller comes with 64 KB of bit-banded SRAM, internal ROM, and 128 KB of Flash memory. The Flash memory controller provides a user-friendly interface, making Flash memory programming a simple task. Flash memory protection can be applied to the Flash memory on a 2-KB block basis.

### 7.1 Block Diagram

Figure 7-1 on page 204 illustrates the internal memory blocks and control logic. The dashed boxes in the figure indicate registers residing in the System Control module.

**Figure 7-1. Internal Memory Block Diagram**

### 7.2 Functional Description

This section describes the functionality of the SRAM, ROM, and Flash memories.

**Note:** The  $\mu$ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the  $\mu$ DMA controller.

## 7.2.1 SRAM

**Note:** The SRAM is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned such that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank incurs a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

The internal SRAM of the Stellaris® devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation. The bit-band base is located at address 0x2200.0000.

The bit-band alias is calculated by using the formula:

$$\text{bit-band alias} = \text{bit-band base} + (\text{byte offset} * 32) + (\text{bit number} * 4)$$

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

$$0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C$$

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, please refer to Chapter 4, “Memory Map” in the *ARM® Cortex™-M3 Technical Reference Manual*.

## 7.2.2 ROM

The internal ROM of the Stellaris® device is located at address 0x0100.0000 of the device memory map. The ROM contains the following components:

- Stellaris® Boot Loader and vector table
- Stellaris® Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error detection functionality

The boot loader is used as an initial program loader (when the Flash memory is empty) as well as an application-initiated firmware upgrade mechanism (by calling back to the boot loader). The Peripheral Driver Library APIs in ROM can be called by applications, reducing Flash memory requirements and freeing the Flash memory to be used for other purposes (such as additional features in the application). Advance Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government and Cyclic Redundancy Check (CRC) is a technique to validate a span of data has the same contents as when previously checked.

### 7.2.2.1 Boot Loader Overview

The Stellaris® Boot Loader is executed from the ROM when the Flash memory is empty and is used to download code to the Flash memory of a device without the use of a debug interface. At any reset that resets the core, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal in Ports A-H as configured in the **Boot Configuration (BOOTCFG)** register. If the ROM boot loader is not selected, code in the

ROM checks address 0x000.0004 to see if the Flash memory has a valid reset vector. If the data at address 0x000.0004 is 0xFFFF.FFFF, then it is assumed that the Flash memory has not yet been programmed, and the core executes the ROM Boot Loader.

The boot loader uses a simple packet interface to provide synchronous communication with the device. The speed of the boot loader is determined by the internal oscillator (PIOSC) frequency as it does not enable the PLL. The following serial interfaces can be used:

- UART0
- SSIO
- I<sup>2</sup>C0

For simplicity, both the data format and communication protocol are identical for all serial interfaces.

**Note:** The Flash-memory-resident version of the Boot Loader also supports CAN and USB.

See the *Stellaris® Boot Loader User's Guide* for information on the boot loader software.

### 7.2.2.2 Stellaris® Peripheral Driver Library

The Stellaris® Peripheral Driver Library contains a file called `driverlib/rom.h` that assists with calling the peripheral driver library functions in the ROM. The detailed description of each function is available in the *Stellaris® ROM User's Guide*. See the "Using the ROM" chapter of the *Stellaris® Peripheral Driver Library User's Guide* for more details on calling the ROM functions and using `driverlib/rom.h`.

A table at the beginning of the ROM points to the entry points for the APIs that are provided in the ROM. Accessing the API through these tables provides scalability; while the API locations may change in future versions of the ROM, the API tables will not. The tables are split into two levels; the main table contains one pointer per peripheral which points to a secondary table that contains one pointer per API that is associated with that peripheral. The main table is located at 0x0100.0010, right after the Cortex-M3 vector table in the ROM.

DriverLib functions are described in detail in the *Stellaris® Peripheral Driver Library User's Guide*.

Additional APIs are available for graphics and USB functions, but are not preloaded into ROM. The Stellaris® Graphics Library provides a set of graphics primitives and a widget set for creating graphical user interfaces on Stellaris® microcontroller-based boards that have a graphical display (for more information, see the *Stellaris® Graphics Library User's Guide*). The Stellaris® USB Library is a set of data types and functions for creating USB Device, Host or On-The-Go (OTG) applications on Stellaris microcontroller-based boards (for more information, see the *Stellaris® USB Library User's Guide*).

### 7.2.2.3 Advanced Encryption Standard (AES) Cryptography Tables

AES is a strong encryption method with reasonable performance and size. AES is fast in both hardware and software, is fairly easy to implement, and requires little memory. AES is ideal for applications that can use pre-arranged keys, such as setup during manufacturing or configuration. Four data tables used by the XySSL AES implementation are provided in the ROM. The first is the forward S-box substitution table, the second is the reverse S-box substitution table, the third is the forward polynomial table, and the final is the reverse polynomial table. See the *Stellaris® ROM User's Guide* for more information on AES.

#### 7.2.2.4 Cyclic Redundancy Check (CRC) Error Detection

The CRC technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily. See the *Stellaris® ROM User's Guide* for more information on CRC.

#### 7.2.3 Flash Memory

At system clock speeds of 50 MHz and below, the Flash memory is read in a single cycle. The Flash memory is organized as a set of 1-KB blocks that can be individually erased. An individual 32-bit word can be programmed to change bits from 1 to 0. In addition, a write buffer provides the ability to concurrently program 32 continuous words in Flash memory. Erasing a block causes the entire contents of the block to be reset to all 1s. The 1-KB blocks are paired into sets of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

---

**Caution – In systems where the microcontroller is frequently powered for less than five minutes, power should be removed from the microcontroller in a controlled manner to ensure proper operation. Software should request permission to power down the part using the USDREQ bit in the Flash Control (FCTL) register and wait to receive an acknowledge from the USDACK bit prior to removing power.**

---

##### 7.2.3.1 Prefetch Buffer

The Flash memory controller has a prefetch buffer that is automatically used when the CPU frequency is greater than 50 MHz. In this mode, the Flash memory operates at half of the system clock. The prefetch buffer fetches two 32-bit words per clock allowing instructions to be fetched with no wait states while code is executing linearly. The fetch buffer includes a branch speculation mechanism that recognizes a branch and avoids extra wait states by not reading the next word pair. Also, short loop branches often stay in the buffer. As a result, some branches can be executed with no wait states. Other branches incur a single wait state.

##### 7.2.3.2 Flash Memory Protection

The user is provided two forms of Flash memory protection per 2-KB Flash memory block in two pairs of 32-bit wide registers. The policy for each protection form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn):** If a bit is set, the corresponding block may be programmed (written) or erased. If a bit is cleared, the corresponding block may not be changed.
- **Flash Memory Protection Read Enable (FMPREn):** If a bit is set, the corresponding block may be executed or read by software or debuggers. If a bit is cleared, the corresponding block may only be executed, and contents of the memory block are prohibited from being read as data.

The policies may be combined as shown in Table 7-1 on page 208.

**Table 7-1. Flash Memory Protection Policy Combinations**

| FMPPEn | FMPREn | Protection                                                                                                                                                                                         |
|--------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0      | Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.                                                                       |
| 1      | 0      | The block may be written, erased or executed, but not read. This combination is unlikely to be used.                                                                                               |
| 0      | 1      | Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access. |
| 1      | 1      | No protection. The block may be written, erased, executed or read.                                                                                                                                 |

A Flash memory access that attempts to read a read-protected block (**FMPREn** bit is set) is prohibited and generates a bus fault. A Flash memory access that attempts to program or erase a program-protected block (**FMPPEn** bit is set) is prohibited and can optionally generate an interrupt (by setting the AMASK bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in "Nonvolatile Register Programming" on page 210.

### 7.2.3.3 Interrupts

The Flash memory controller can generate interrupts when the following conditions are observed:

- Programming Interrupt - signals when a program or erase action is complete.
- Access Interrupt - signals when a program or erase action has been attempted on a 2-kB block of memory that is protected by its corresponding **FMPPEn** bit.

The interrupt events that can trigger a controller-level interrupt are defined in the **Flash Controller Masked Interrupt Status (FCMIS)** register (see page 218) by setting the corresponding MASK bits. If interrupts are not used, the raw interrupt status is always visible via the **Flash Controller Raw Interrupt Status (FCRIS)** register (see page 217).

Interrupts are always cleared (for both the **FCMIS** and **FCRIS** registers) by writing a 1 to the corresponding bit in the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register (see page 219).

## 7.3 Flash Memory Initialization and Configuration

### 7.3.1 Flash Memory Programming

The Stellaris® devices provide a user-friendly interface for Flash memory programming. All erase/program operations are handled via three registers: **Flash Memory Address (FMA)**, **Flash Memory Data (FMD)**, and **Flash Memory Control (FMC)**. Note that if the debug capabilities of the microcontroller have been deactivated, resulting in a "locked" state, a recovery sequence must be performed in order to reactivate the debug module. See "Recovering a "Locked" Microcontroller" on page 93.

---

**Caution** – The Flash memory is divided into sectors of electrically separated address ranges of 4 KB each, aligned on 4 KB boundaries. Erase/program operations on a 1-KB page have an electrical effect on the other three 1-KB pages within the sector. A specific 1-KB page must be erased after 6 total erase/program cycles occur to the other pages within its 4-KB sector. The following sequence of operations on a 4-KB sector of Flash memory (Page 0..3) provides an example:

- Page 3 is erase and programmed with values.
  - Page 0, Page 1, and Page 2 are erased and then programmed with values. At this point Page 3 has been affected by 3 erase/program cycles.
  - Page 0, Page 1, and Page 2 are again erased and then programmed with values. At this point Page 3 has been affected by 6 erase/program cycles.
  - If the contents of Page 3 must continue to be valid, Page 3 must be erased and reprogrammed before any other page in this sector has another erase or program operation.
- 

#### 7.3.1.1 To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the Flash memory write key and the WRITE bit (a value of 0xA442.0001) to the **FMC** register.
4. Poll the **FMC** register until the WRITE bit is cleared.

---

**Important:** To ensure proper operation, two writes to the same word must be separated by an ERASE. The following two sequences are allowed:

- ERASE -> PROGRAM value -> PROGRAM 0x0000.0000
- ERASE -> PROGRAM value -> ERASE

The following sequence is NOT allowed:

- ERASE -> PROGRAM value -> PROGRAM value
- 

#### 7.3.1.2 To perform an erase of a 1-KB page

1. Write the page address to the **FMA** register.
2. Write the Flash memory write key and the ERASE bit (a value of 0xA442.0002) to the **FMC** register.
3. Poll the **FMC** register until the ERASE bit is cleared.

#### 7.3.1.3 To perform a mass erase of the Flash memory

1. Write the Flash memory write key and the MERASE bit (a value of 0xA442.0004) to the **FMC** register.

2. Poll the **FMC** register until the MERASE bit is cleared.

### 7.3.2 32-Word Flash Memory Write Buffer

A 32-word write buffer provides the capability to perform faster write accesses to the Flash memory by concurrently programming 32 words with a single buffered Flash memory write operation. The buffered Flash memory write operation takes the same amount of time as the single word write operation controlled by bit 0 in the **FMC** register. The data for the buffered write is written to the **Flash Write Buffer (FWBn)** registers.

The registers are 32-word aligned with Flash memory, and therefore the register **FWB0** corresponds with the address in **FMA** where bits [6:0] of **FMA** are all 0. **FWB1** corresponds with the address in **FMA** + 0x4 and so on. Only the **FWBn** registers that have been updated since the previous buffered Flash memory write operation are written. The **Flash Write Buffer Valid (FWBVAL)** register shows which registers have been written since the last buffered Flash memory write operation. This register contains a bit for each of the 32 **FWBn** registers, where bit[n] of **FWBVAL** corresponds to **FWBn**. The **FWBn** register has been updated if the corresponding bit in the **FWBVAL** register is set.

#### 7.3.2.1 To program 32 words with a single buffered Flash memory write operation

1. Write the source data to the **FWBn** registers.
2. Write the target address to the **FMA** register. This must be a 32-word aligned address (that is, bits [6:0] in **FMA** must be 0s).
3. Write the Flash memory write key and the WRBUF bit (a value of 0xA442.0001) to the **FMC2** register.
4. Poll the **FMC2** register until the WRBUF bit is cleared.

### 7.3.3 Nonvolatile Register Programming

This section discusses how to update registers that are resident within the Flash memory itself. These registers exist in a separate space from the main Flash memory array and are not affected by an ERASE or MASS ERASE operation. The bits in these registers can be changed from 1 to 0 with a write operation. The register contents are unaffected by any reset condition except power-on reset, which returns the register contents to 0xFFFF.FFFF. By committing the register values using the COMT bit in the **FMC** register, the register contents become nonvolatile and are therefore retained following power cycling. Once the register contents are committed, the only way to restore the factory default values is to perform the sequence described in "Recovering a "Locked" Microcontroller" on page 93.

With the exception of the **Boot Configuration (BOOTCFG)** register, the settings in these registers can be tested before committing them to Flash memory. For the **BOOTCFG** register, the data to be written is loaded into the **FMD** register before it is committed. The **FMD** register is read only and does not allow the **BOOTCFG** operation to be tried before committing it to nonvolatile memory.

---

**Important:** The Flash memory resident registers can only have bits changed from 1 to 0 by user programming and can only be committed once. After being committed, these registers can only be restored to their factory default values only by performing the sequence described in "Recovering a "Locked" Microcontroller" on page 93. The mass erase of the main Flash memory array caused by the sequence is performed prior to restoring these registers.

---

In addition, the **USER\_REG0**, **USER\_REG1**, **USER\_REG2**, **USER\_REG3**, and **BOOTCFG** registers each use bit 31 (NW) to indicate that they have not been committed and bits in the register may be changed from 1 to 0. Table 7-2 on page 211 provides the **FMA** address required for commitment of each of the registers and the source of the data to be written when the **FMC** register is written with a value of 0xA442.0008. After writing the COMT bit, the user may poll the **FMC** register to wait for the commit operation to complete.

**Table 7-2. User-Programmable Flash Memory Resident Registers**

| Register to be Committed | FMA Value   | Data Source |
|--------------------------|-------------|-------------|
| FMPRE0                   | 0x0000.0000 | FMPRE0      |
| FMPRE1                   | 0x0000.0002 | FMPRE1      |
| FMPPE0                   | 0x0000.0001 | FMPPE0      |

## 7.4 Register Map

Table 7-3 on page 211 lists the ROM Controller register and the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The **FMA**, **FMD**, **FMC**, **FCRIS**, **FCIM**, **FCMISC**, **FMC2**, **FWBVAL**, and **FWBn** register offsets are relative to the Flash memory control base address of 0x400F.D000. The ROM and Flash memory protection register offsets are relative to the System Control base address of 0x400F.E000.

**Table 7-3. Flash Register Map**

| Offset                                               | Name   | Type  | Reset       | Description                                        | See page |

## 7.5 Flash Memory Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

## Register 1: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned address and specifies which page is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

### Flash Memory Address (FMA)

Base 0x400F.D000

Offset 0x000

Type R/W, reset 0x0000.0000

|       | 31       | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16     |
|-------|----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|--------|
|       | reserved |     |     |     |     |     |     |     |     |     |     |     |     |     |     | OFFSET |
| Type  | RO       | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | RO  | R/W    |
| Reset | 0        | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0      |

|       | OFFSET   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |        |
| Type  | R/W      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W    |
| Reset | 0        | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0      |

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                    |
|-----------|----------|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:17     | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                  |
| 16:0      | OFFSET   | R/W  | 0x0   | Address Offset<br><br>Address offset in Flash memory where operation is performed, except for nonvolatile registers (see "Nonvolatile Register Programming" on page 210 for details on values for this field). |

Register 2: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle or read during the read cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during erase cycles.

Flash Memory Data (FMD)

Base 0x400F.D000  
Offset 0x004  
Type R/W, reset 0x0000.0000

| Bit/Field | Name | Type | Reset       | Description                     |
|-----------|------|------|-------------|---------------------------------|
| 31:0      | DATA | R/W  | 0x0000.0000 | Data Value                      |
|           |      |      |             | Data value for write operation. |

### Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 213). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 214) is written to the specified address.

This register must be the final register written and initiates the memory operation. The four control bits in the lower byte of this register are used to initiate memory operations.

Care must be taken not to set multiple control bits as the results of such an operation are unpredictable.

## Register 4: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C

This register indicates that the Flash memory controller has an interrupt condition. An interrupt is sent to the interrupt controller only if the corresponding **FCIM** register bit is set.

### Flash Controller Raw Interrupt Status (FCRIS)

Base 0x400F.D000

Offset 0x00C

Type RO, reset 0x0000.0000

## Register 5: Flash Controller Interrupt Mask (FCIM), offset 0x010

This register controls whether the Flash memory controller generates interrupts to the controller.

### Flash Controller Interrupt Mask (FCIM)

Base 0x400F.D000

Offset 0x010

Type R/W, reset 0x0000.0000

## Register 6: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014

This register provides two functions. First, it reports the cause of an interrupt by indicating which interrupt source or sources are signalling the interrupt. Second, it serves as the method to clear the interrupt reporting.

### Flash Controller Masked Interrupt Status and Clear (FCMISC)

Base 0x400F.D000

Offset 0x014

Type R/W1C, reset 0x0000.0000

## Register 7: Flash Memory Control 2 (FMC2), offset 0x020

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 213). If the access is a write access, the data contained in the **Flash Write Buffer (FWB)** registers is written.

This register must be the final register written as it initiates the memory operation.

This bit is used to start a buffered write to Flash memory.

#### Value Description

1 Set this bit to write the data stored in the **FWBn** registers to the location specified by the contents of the **FMA** register.

When read, a 1 indicates that the previous buffered Flash memory write access is not complete.

0 A write of 0 has no effect on the state of this bit.

When read, a 0 indicates that the previous buffered Flash memory write access is complete.

A buffered Flash memory write can take up to 4 ms.

## Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030

This register provides a bitwise status of which **FWBn** registers have been written by the processor since the last write of the Flash memory write buffer. The entries with a 1 are written on the next write of the Flash memory write buffer. This register is cleared after the write operation by hardware. A protection violation on the write operation also clears this status.

Software can program the same 32 words to various Flash memory locations by setting the FWB[n] bits after they are cleared by the write operation. The next write operation then uses the same data as the previous one. In addition, if a **FWBn** register change should not be written to Flash memory, software can clear the corresponding FWB[n] bit to preserve the existing data when the next write operation occurs.

### Flash Write Buffer Valid (FWBVAL)

#### Value Description

- |   |                                                                                                                                           |
|---|-------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The corresponding <b>FWBn</b> register has been updated since the last buffer write operation and is ready to be written to Flash memory. |
| 0 | The corresponding <b>FWBn</b> register has no new data to be written.                                                                     |

Bit 0 corresponds to **FWB0**, offset 0x100, and bit 31 corresponds to **FWB31**, offset 0x13C.

## Register 9: Flash Write Buffer n (FWBn), offset 0x100 - 0x17C

These 32 registers hold the contents of the data to be written into the Flash memory on a buffered Flash memory write operation. The offset selects one of the 32-bit registers. Only **FWBn** registers that have been updated since the preceding buffered Flash memory write operation are written into the Flash memory, so it is not necessary to write the entire bank of registers in order to write 1 or 2 words. The **FWBn** registers are written into the Flash memory with the **FWB0** register corresponding to the address contained in **FMA**. **FWB1** is written to the address **FMA+0x4** etc. Note that only data bits that are 0 result in the Flash memory being modified. A data bit that is 1 leaves the content of the Flash memory bit at its previous value.

## Register 10: Flash Control (FCTL), offset 0x0F8

This register is used to ensure that the microcontroller is powered down in a controlled fashion in systems where power is cycled more frequently than once every five minutes. The USDREQ bit should be set to indicate that power is going to be turned off. Software should poll the USDACK bit to determine when it is acceptable to power down.

## 7.6 Memory Register Descriptions (System Control Offset)

The remainder of this section lists and describes the registers that reside in Flash memory, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

## Register 11: ROM Control (RMCTL), offset 0x0F0

This register provides control of the ROM controller state. This register offset is relative to the System Control base address of 0x400F.E000.

### ROM Control (RMCTL)

Base 0x400F.E000

Offset 0x0F0

Type R/W1C, reset -

|-----------|----------|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1      | reserved | RO    | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | BA       | R/W1C | -          | Boot Alias                                                                                                                                                                                    |

At reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal as configured in the **BOOTCFG** register. If the ROM boot loader is not selected, the system control module checks address 0x000.0004 to see if the Flash memory has a valid reset vector. If the data at address 0x0000.0004 is 0xFFFF.FFFF, then it is assumed that the Flash memory has not yet been programmed, and this bit is then set by hardware so that the on-chip ROM appears at address 0x0.

#### Value Description

- |   |                                                                                                                                    |
|---|------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The microcontroller's ROM appears at address 0x0. This bit is set automatically if the data at address 0x0000.0004 is 0xFFFF.FFFF. |
| 0 | The Flash memory is at address 0x0.                                                                                                |

This bit is cleared by writing a 1 to this bit position.

**Register 12: ROM Version Register (RMVER), offset 0x0F4****Note:** Offset is relative to System Control base address of 0x400FE000.

A 32-bit read-only register containing the ROM content version information.

## ROM Version Register (RMVER)

### Register 13: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

**Note:** This register is aliased for backwards compatability.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see the "Flash Memory Protection" section.

#### Flash Memory Protection Read Enable 0 (FMPRE0)

|           |             |      |            | Configures 2-KB flash blocks to be read or executed only. The policies may be combined as shown in the table "Flash Protection Policy Combinations". |
|           |             |      |            | Value      Description                                                                                                                               |
|           |             |      |            | 0xFFFFFFFF Bits [31:0] each enable protection on a 2-KB block of Flash memory up to the total of 64 KB.                                              |

## Register 14: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

**Note:** This register is aliased for backwards compatability.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREN** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPPEN** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEN** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see the "Flash Memory Protection" section.

|-----------|-------------|------|------------|--------------------------|
| 31:0      | PROG_ENABLE | R/W  | 0xFFFFFFFF | Flash Programming Enable |

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

| Value      | Description                                                                                  |
|------------|----------------------------------------------------------------------------------------------|
| 0xFFFFFFFF | Bits [31:0] each enable protection on a 2-KB block of Flash memory up to the total of 64 KB. |

**Register 15: Boot Configuration (BOOTCFG), offset 0x1D0**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides configuration of a GPIO pin to enable the ROM Boot Loader as well as a write-once mechanism to disable external debugger access to the device. Upon reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal from Ports A-H as configured by the bits in this register. If the EN bit is set or the specified pin does not have the required polarity, the system control module checks address 0x000.0004 to see if the Flash memory has a valid reset vector. If the data at address 0x000.0004 is 0xFFFF.FFFF, then it is assumed that the Flash memory has not yet been programmed, and the core executes the ROM Boot Loader. The DBG0 bit (bit 0) is set to 0 from the factory and the DBG1 bit (bit 1) is set to 1, which enables external debuggers. Clearing the DBG1 bit disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The NW bit (bit 31) indicates that the register has not yet been committed and is controlled through hardware to ensure that the register is only committed once. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. The only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter.

**Register 16: User Register 0 (USER\_REG0), offset 0x1E0**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be committed once. Bit 31 indicates that the register is available to be committed and is controlled through hardware to ensure that the register is only committed once. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device. The only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG section.

**Register 20: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREN** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 64 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

|-----------|-------------|------|------------|-------------------|
| 31:0      | READ_ENABLE | R/W  | 0xFFFFFFFF | Flash Read Enable |

Configures 2-KB flash blocks to be read or executed only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

| Value | Description |
|-------|-------------|
|-------|-------------|

|            |                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------|
| 0xFFFFFFFF | Bits [31:0] each enable protection on a 2-KB block of Flash memory in memory range from 65 to 128 KB. |
|------------|-------------------------------------------------------------------------------------------------------|

**Register 21: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREN** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 128 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

| 31:0 | READ_ENABLE | R/W | 0x00000000 | Flash Read Enable |
|------|-------------|-----|------------|-------------------|

Configures 2-KB flash blocks to be read or executed only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

| Value | Description |
|-------|-------------|
|-------|-------------|

|            |                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------|
| 0x00000000 | Bits [31:0] each enable protection on a 2-KB block of Flash memory in the range from 129 to 192 KB. |
|------------|-----------------------------------------------------------------------------------------------------|

**Register 22: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPREn** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 192 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

**Flash Memory Protection Read Enable 3 (FMPRE3)**

Base 0x400F.E000

Offset 0x20C

Type R/W, reset 0x0000.0000

| Bit/Field | Name | Type | Reset | Description |

|------------|-----------------------------------------------------------------------------------------------------|
| 0x00000000 | Bits [31:0] each enable protection on a 2-KB block of Flash memory in the range from 193 to 256 KB. |
|------------|-----------------------------------------------------------------------------------------------------|

## Register 23: Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPPE<sub>n</sub>** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPPE<sub>n</sub>** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPPE<sub>n</sub>** and **FMPPE<sub>n</sub>** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 64 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

| 0xFFFFFFFF | Bits [31:0] each enable protection on a 2-KB block of Flash memory in memory range from 65 to 128 KB. |

## Register 24: Flash Memory Protection Program Enable 2 (FMPPE2), offset 0x408

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPPE<sub>n</sub>** stores the execute-only bits). Flash memory up to a total of 64 KB is controlled by this register. Other **FMPPE<sub>n</sub>** registers (if any) provide protection for other 64K blocks. This register is loaded during the power-on reset sequence. The factory settings for the **FMPPE<sub>n</sub>** and **FMPPE<sub>n</sub>** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. If the Flash memory size on the device is less than 128 KB, this register usually reads as zeroes, but software should not rely on these bits to be zero. For additional information, see the "Flash Memory Protection" section.

## 8 Micro Direct Memory Access (μDMA)

The LM3S5791 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μDMA). The μDMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the available bus bandwidth. The μDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μDMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable μDMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules: GP Timer, USB, UART, ADC, EPI, SSI, I<sup>2</sup>S
  - Primary and secondary channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable bus arbitration scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between μDMA controller and the processor core
  - μDMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment

- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

## 8.1 Block Diagram

Figure 8-1.  $\mu$ DMA Block Diagram

## 8.2 Functional Description

The  $\mu$ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M3 processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The  $\mu$ DMA controller's usage of the bus is always subordinate to the processor core, so it never holds up a bus transaction by the processor. Because the  $\mu$ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly enhance the ability of the processor core and the  $\mu$ DMA controller to efficiently share the on-chip bus, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allow both the processor core and the  $\mu$ DMA controller to access the bus and perform simultaneous data transfers.

The  $\mu$ DMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the  $\mu$ DMA controller.

Each peripheral function that is supported has a dedicated channel on the  $\mu$ DMA controller that can be configured independently. The  $\mu$ DMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the  $\mu$ DMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The  $\mu$ DMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the  $\mu$ DMA controller rearbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a  $\mu$ DMA service request.

## 8.2.1 Channel Assignments

$\mu$ DMA channels 0-31 are assigned to peripherals according to the following table. The **DMA Channel Assignment (DMACHASGN)** register (see page 289) can be used to specify the primary or secondary assignment. If the primary function is not available on this microcontroller, the secondary function becomes the primary function. If the secondary function is not available, the primary function is the only option.

**Note:** Channels noted in the table as "Available for software" may be assigned to peripherals in the future. However, they are currently available for software use. Channel 30 is dedicated for software use.

The USB endpoints mapped to  $\mu$ DMA channels 0-3 can be changed with the **USBDMASEL** register (see page 947).

If a channel is marked with "\*" below and is configured to transfer data with a software request using the **DMASWREQ** register, this channel must also be enabled in the **DMAENASET** register.

**Table 8-1.  $\mu$ DMA Channel Assignments**

| $\mu$ DMA Channel | Primary Assignment       | Secondary Assignment      |
|-------------------|--------------------------|---------------------------|
| 0                 | USB Endpoint 1 Receive   | UART2 Receive*            |
| 1                 | USB Endpoint 1 Transmit  | UART2 Transmit*           |
| 2                 | USB Endpoint 2 Receive   | General-Purpose Timer 3A* |
| 3                 | USB Endpoint 2 Transmit  | General-Purpose Timer 3B* |
| 4                 | USB Endpoint 3 Receive   | General-Purpose Timer 2A* |
| 5                 | USB Endpoint 3 Transmit  | General-Purpose Timer 2B* |
| 6                 | Available for software   | General-Purpose Timer 2A* |

## 8.2.2 Priority

The  $\mu$ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

## 8.2.3 Arbitration Size

When a  $\mu$ DMA channel requests a transfer, the  $\mu$ DMA controller arbitrates among all the channels making a request and services the  $\mu$ DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before re-arbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the  $\mu$ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority  $\mu$ DMA channel uses a large arbitration size, the latency for higher priority channels is increased because the  $\mu$ DMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of  $\mu$ DMA channel priority, not arbitration for the bus. When the  $\mu$ DMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the  $\mu$ DMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

## 8.2.4 Request Types

The  $\mu$ DMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The  $\mu$ DMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the  $\mu$ DMA channel has been set up for a burst

transfer, then the burst request takes precedence. See Table 8-2, which shows how each peripheral supports the two request types.

**Table 8-2. Request Type Support**

| Peripheral            | Single Request Signal | Burst Request Signal         |
|-----------------------|-----------------------|------------------------------|
| USB TX                | None                  | FIFO TXRDY                   |
| USB RX                | None                  | FIFO RXRDY                   |
| UART TX               | TX FIFO Not Full      | TX FIFO Level (configurable) |
| UART RX               | RX FIFO Not Empty     | RX FIFO Level (configurable) |
| SSI TX                | TX FIFO Not Full      | TX FIFO Level (fixed at 4)   |
| SSI RX                | RX FIFO Not Empty     | RX FIFO Level (fixed at 4)   |
| ADC                   | None                  | Sequencer IE bit             |
| General-Purpose Timer | None                  | Raw interrupt pulse          |
| I <sup>2</sup> S TX   | None                  | FIFO service request         |
| I <sup>2</sup> S RX   | None                  | FIFO service request         |
| EPI WFIFO             | None                  | WFIFO Level (configurable)   |
| EPI NBRFIFO           | None                  | NBRFIFO Level (configurable) |

#### 8.2.4.1 Single Request

When a single request is detected, and not a burst request, the  $\mu$ DMA controller transfers one item and then stops to wait for another request.

#### 8.2.4.2 Burst Request

When a burst request is detected, the  $\mu$ DMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached. A burst transfer runs to completion once it is started, and cannot be interrupted, even by a higher priority channel. Burst transfers complete in a shorter time than the same number of non-burst transfers.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the  $\mu$ DMA controller only responds to burst requests for that channel.

#### 8.2.5 Channel Configuration

The  $\mu$ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each  $\mu$ DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 8-3 on page 246 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table, and all the alternate structures are in the second half of the table. The primary entry

is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

**Table 8-3. Control Structure Memory Map**

| Offset | Channel       |
|--------|---------------|
| 0x0    | 0, Primary    |
| 0x10   | 1, Primary    |
| ...    | ...           |
| 0x1F0  | 31, Primary   |
| 0x200  | 0, Alternate  |
| 0x210  | 1, Alternate  |
| ...    | ...           |
| 0x3F0  | 31, Alternate |

Table 8-4 shows an individual control structure entry in the control table. Each entry is aligned on a 16-byte boundary. The entry contains four long words: the source end pointer, the destination end pointer, the control word, and an unused entry. The end pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

**Table 8-4. Channel Control Structure**

| Offset | Description             |
|--------|-------------------------|
| 0x000  | Source End Pointer      |
| 0x004  | Destination End Pointer |
| 0x008  | Control Word            |
| 0x00C  | Unused                  |

The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in “ $\mu$ DMA Channel Control Structure” on page 263. The  $\mu$ DMA controller updates the transfer size and transfer mode fields as

the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer mode indicates "stopped." Because the control word is modified by the  $\mu$ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a  $\mu$ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set (DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete  $\mu$ DMA transfer, the controller automatically disables the channel.

## 8.2.6 Transfer Modes

The  $\mu$ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

### 8.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the  $\mu$ DMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the  $\mu$ DMA controller updates the control word to set the mode to Stop.

### 8.2.6.2 Basic Mode

In Basic mode, the  $\mu$ DMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a  $\mu$ DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only the number of transfers specified by the ARBSIZE field in the **DMA Channel Control Word (DMACHCTL)** register is transferred on a software request, even if there is more data to transfer.

When all of the items have been transferred using Basic mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 8.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the  $\mu$ DMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 8.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the  $\mu$ DMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 8-2 for an example showing operation in Ping-Pong mode.

Figure 8-2. Example of Ping-Pong  $\mu$ DMA Transaction

### 8.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather  $\mu$ DMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The  $\mu$ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Basic transfer mode. Once the last transfer is performed using Basic mode, the  $\mu$ DMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a  $\mu$ DMA request.

By programming the  $\mu$ DMA controller using this method, a set of arbitrary transfers can be performed based on a single  $\mu$ DMA request.

Refer to Figure 8-3 on page 250 and Figure 8-4 on page 251, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory is copied together into one buffer. Figure 8-3 on page 250 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-4 on page 251 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 8-3. Memory Scatter-Gather, Setup and Configuration

## NOTES:

1. Application has a need to copy data items from three separate locations in memory into one combined buffer.
2. Application sets up  $\mu$ DMA "task list" in memory, which contains the pointers and control configuration for three  $\mu$ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the  $\mu$ DMA controller.

**Figure 8-4. Memory Scatter-Gather,  $\mu$ DMA Copy Sequence**

Using the channel's primary control structure, the  $\mu$ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer C to the destination buffer.

### 8.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a  $\mu$ DMA request. Upon detecting a request from the peripheral, the  $\mu$ DMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the next transfer is started only if the peripheral again asserts a  $\mu$ DMA request. The  $\mu$ DMA controller continues to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt is generated only after the last transfer.

By using this method, the  $\mu$ DMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 8-5 on page 253 and Figure 8-6 on page 254, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 8-5 on page 253 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-6 on page 254 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 8-5. Peripheral Scatter-Gather, Setup and Configuration

## NOTES:

1. Application has a need to copy data items from three separate locations in memory into a peripheral data register.
2. Application sets up  $\mu$ DMA "task list" in memory, which contains the pointers and control configuration for three  $\mu$ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the  $\mu$ DMA controller.

Figure 8-6. Peripheral Scatter-Gather,  $\mu$ DMA Copy Sequence

## 8.2.7 Transfer Size and Increment

The  $\mu$ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 8-5 shows the configuration to read from a peripheral that supplies 8-bit data.

**Table 8-5.  $\mu$ DMA Read Example: 8-Bit Peripheral**

| Field                         | Configuration                    |
|-------------------------------|----------------------------------|
| Source data size              | 8 bits                           |
| Destination data size         | 8 bits                           |
| Source address increment      | No increment                     |
| Destination address increment | Byte                             |
| Source end pointer            | Peripheral read FIFO register    |
| Destination end pointer       | End of the data buffer in memory |

## 8.2.8 Peripheral Interface

Each peripheral that supports  $\mu$ DMA has a single request and/or burst request signal that is asserted when the peripheral is ready to transfer data (see Table 8-2 on page 245). The request signal can be disabled or enabled using the **DMA Channel Request Mask Set (DMAREQMASKSET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The  $\mu$ DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the  $\mu$ DMA channel is configured correctly and enabled, and the peripheral asserts the request signal, the  $\mu$ DMA controller begins the transfer.

When a  $\mu$ DMA transfer is complete, the  $\mu$ DMA controller generates an interrupt, see “Interrupts and Errors” on page 256 for more information.

For more information on how a specific peripheral interacts with the  $\mu$ DMA controller, refer to the DMA Operation section in the chapter that discusses that peripheral.

## 8.2.9 Software Request

One  $\mu$ DMA channel is dedicated to software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a  $\mu$ DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral  $\mu$ DMA channel, then the completion interrupt occurs on the interrupt vector for the peripheral instead of the software interrupt vector. Any channel may be used for software requests as long as the corresponding peripheral is not using  $\mu$ DMA for data transfer.

## 8.2.10 Interrupts and Errors

When a  $\mu$ DMA transfer is complete, the  $\mu$ DMA controller generates a completion interrupt on the interrupt vector of the peripheral. Therefore, if  $\mu$ DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the  $\mu$ DMA transfer completion interrupt. If the transfer uses the software  $\mu$ DMA channel, then the completion interrupt occurs on the dedicated software  $\mu$ DMA interrupt vector (see Table 8-6).

When  $\mu$ DMA is enabled for a peripheral, the  $\mu$ DMA controller stops the normal transfer interrupts for a peripheral from reaching the interrupt controller (the interrupts are still reported in the peripheral's interrupt registers). Thus, when a large amount of data is transferred using  $\mu$ DMA, instead of receiving multiple interrupts from the peripheral as data flows, the interrupt controller receives only one interrupt when the transfer is complete. Unmasked peripheral error interrupts continue to be sent to the interrupt controller.

If the  $\mu$ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the  $\mu$ DMA channel that caused the error and generates an interrupt on the  $\mu$ DMA error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The ERRCLR bit is set if an error occurred. The error can be cleared by writing a 1 to the ERRCLR bit.

Table 8-6 shows the dedicated interrupt assignments for the  $\mu$ DMA controller.

**Table 8-6.  $\mu$ DMA Interrupt Assignments**

| Interrupt | Assignment                          |
|-----------|-------------------------------------|
| 46        | $\mu$ DMA Software Channel Transfer |
| 47        | $\mu$ DMA Error                     |

## 8.3 Initialization and Configuration

### 8.3.1 Module Initialization

Before the  $\mu$ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. The  $\mu$ DMA peripheral must be enabled in the System Control block. To do this, set the UDMA bit of the System Control **RCGC2** register (see page 191).
2. Enable the  $\mu$ DMA controller by setting the MASTEREN bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

### 8.3.2 Configuring a Memory-to-Memory Transfer

$\mu$ DMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

#### 8.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

### 8.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 8-7.

**Table 8-7. Channel Control Structure Offsets for Channel 30**

| Offset                     | Description                        |
|----------------------------|------------------------------------|
| Control Table Base + 0x1E0 | Channel 30 Source End Pointer      |
| Control Table Base + 0x1E4 | Channel 30 Destination End Pointer |
| Control Table Base + 0x1E8 | Channel 30 Control Word            |

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 8-8.

**Table 8-8. Channel Control Word Configuration for Memory Transfer Example**

| Field in DMACHCTL | Bits  | Value | Description                          |
|-------------------|-------|-------|--------------------------------------|
| DSTINC            | 31:30 | 2     | 32-bit destination address increment |
| DSTSIZE           | 29:28 | 2     | 32-bit destination data size         |
| SRCINC            | 27:26 | 2     | 32-bit source address increment      |
| SRCSIZE           | 25:24 | 2     | 32-bit source data size              |
| reserved          | 23:18 | 0     | Reserved                             |
| ARBSIZE           | 17:14 | 3     | Arbitrates after 8 transfers         |
| XFERSIZE          | 13:4  | 255   | Transfer 256 items                   |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type           |
| XFERMODE          | 2:0   | 2     | Use Auto-request transfer mode       |

### 8.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The μDMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the XFERMODE field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

### 8.3.3 Configuring a Peripheral for Simple Transmit

This example configures the μDMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses μDMA channel 7.

#### 8.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μDMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μDMA controller to recognize requests for this channel.

#### 8.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using μDMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 8-9.

**Table 8-9. Channel Control Structure Offsets for Channel 7**

| Offset                     | Description                       |
|----------------------------|-----------------------------------|
| Control Table Base + 0x070 | Channel 7 Source End Pointer      |
| Control Table Base + 0x074 | Channel 7 Destination End Pointer |
| Control Table Base + 0x078 | Channel 7 Control Word            |

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 8-10.

**Table 8-10. Channel Control Word Configuration for Peripheral Transmit Example**

| Field in DMACHCTL | Bits  | Value | Description                            |
|-------------------|-------|-------|----------------------------------------|
| DSTINC            | 31:30 | 3     | Destination address does not increment |
| DSTSIZE           | 29:28 | 0     | 8-bit destination data size            |
| SRCINC            | 27:26 | 0     | 8-bit source address increment         |
| SRCSIZE           | 25:24 | 0     | 8-bit source data size                 |
| reserved          | 23:18 | 0     | Reserved                               |
| ARBSIZE           | 17:14 | 2     | Arbitrates after 4 transfers           |
| XFERSIZE          | 13:4  | 63    | Transfer 64 items                      |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type             |
| XFERMODE          | 2:0   | 1     | Use Basic transfer mode                |

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET [ 7 ] bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

### 8.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The  $\mu$ DMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a  $\mu$ DMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the  $\mu$ DMA controller disables the channel and sets the XFERMODE field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the XFERMODE field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral interrupt handler receives an interrupt when the entire transfer is complete.

## 8.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the  $\mu$ DMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses  $\mu$ DMA channel 8.

### 8.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.

2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

#### 8.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the  $\mu$ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 8-11.

**Table 8-11. Primary and Alternate Channel Control Structure Offsets for Channel 8**

| Offset                     | Description                                 |
|----------------------------|---------------------------------------------|
| Control Table Base + 0x080 | Channel 8 Primary Source End Pointer        |
| Control Table Base + 0x084 | Channel 8 Primary Destination End Pointer   |
| Control Table Base + 0x088 | Channel 8 Primary Control Word              |
| Control Table Base + 0x280 | Channel 8 Alternate Source End Pointer      |
| Control Table Base + 0x284 | Channel 8 Alternate Destination End Pointer |
| Control Table Base + 0x288 | Channel 8 Alternate Control Word            |

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 8-12.
2. Program the alternate channel control word at offset 0x288 according to Table 8-12.

**Table 8-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example**

| Field in DMACHCTL | Bits  | Value | Description                         |
|-------------------|-------|-------|-------------------------------------|
| DSTINC            | 31:30 | 0     | 8-bit destination address increment |
| DSTSIZE           | 29:28 | 0     | 8-bit destination data size         |
| SRCINC            | 27:26 | 3     | Source address does not increment   |
| SRCSIZE           | 25:24 | 0     | 8-bit source data size              |
| reserved          | 23:18 | 0     | Reserved                            |
| ARBSIZE           | 17:14 | 3     | Arbitrates after 8 transfers        |
| XFERSIZE          | 13:4  | 63    | Transfer 64 items                   |
| NXTUSEBURST       | 3     | 0     | N/A for this transfer type          |
| XFERMODE          | 2:0   | 3     | Use Ping-Pong transfer mode         |

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET[8] bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

#### 8.3.4.3 Configure the Peripheral Interrupt

An interrupt handler should be configured when using  $\mu$ DMA Ping-Pong mode, it is best to use an interrupt handler. However, the Ping-Pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

#### 8.3.4.4 Enable the $\mu$ DMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

#### 8.3.4.5 Process Interrupts

The  $\mu$ DMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the  $\mu$ DMA request signal, the  $\mu$ DMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the XFERMODE field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:
  - a. Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.

- b. Reprogram the primary channel control word at offset 0x88 according to Table 8-12 on page 261.
  2. Read the alternate channel control word at offset 0x288 and check the XFERMODE field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
    - a. Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
    - b. Reprogram the alternate channel control word at offset 0x288 according to Table 8-12 on page 261.

### 8.3.5 Configuring Channel Assignments

Channel assignments for each μDMA channel can be changed using the **DMACHASGN** register. Each bit represents a μDMA channel. If the bit is set, then the secondary function is used for the channel.

Refer to Table 8-1 on page 243 for channel assignments.

For example, to use SS11 Receive on channel 8 instead of UART0, set bit 8 of the **DMACHASGN** register.

## 8.4 Register Map

Table 8-13 on page 262 lists the μDMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, that is, the base address is n/a (not applicable). In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 245 and Table 8-3 on page 246 for a description of how the entries in the channel control table are located in memory. The μDMA register addresses are given as a hexadecimal increment, relative to the μDMA base address of 0x400F.F000. Note that the μDMA module clock must be enabled before the registers can be programmed (see page 191).

**Table 8-13. μDMA Register Map**

| Offset                                                                         | Name        | Type | Reset       | Description                                 | See page |
|--------------------------------------------------------------------------------|-------------|------|-------------|---------------------------------------------|----------|
| <b>μDMA Channel Control Structure (Offset from Channel Control Table Base)</b> |             |      |             |                                             |          |
| 0x000                                                                          | DMASRCENDP  | R/W  | -           | DMA Channel Source Address End Pointer      | 264      |
| 0x004                                                                          | DMADSTENDP  | R/W  | -           | DMA Channel Destination Address End Pointer | 265      |
| 0x008                                                                          | DMACHCTL    | R/W  | -           | DMA Channel Control Word                    | 266      |

## 8.5 $\mu$ DMA Channel Control Structure

The  $\mu$ DMA Channel Control Structure holds the transfer settings for a  $\mu$ DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 245 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. Each channel has a primary and alternate structure. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

**Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000**

**DMA Channel Source Address End Pointer (DMASRCENDP)** is part of the Channel Control Structure and is used to specify the source address for a μDMA transfer.

The μDMA controller can transfer data to and from the on-chip SRAM. However, because the Flash memory and ROM are located on a separate internal bus, it is not possible to transfer data from the Flash memory or ROM with the μDMA controller.

**Note:** The offset specified is from the base address of the control structure in system memory, not the μDMA module base address.

DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a  
Offset 0x000  
Type R/W, reset -

| Bit/Field | Name | Type | Reset | Description                                                                                                                                                                                                                                                                    |
|-----------|------|------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0      | ADDR | R/W  | -     | Source Address End Pointer                                                                                                                                                                                                                                                     |
|           |      |      |       | This field points to the last address of the μDMA transfer source (inclusive). If the source address is not incrementing (the SRCINC field in the <b>DMACHCTL</b> register is 0x3), then this field points at the source location itself (such as a peripheral data register). |

Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

DMA Channel Destination Address End Pointer (DMADSTENDP) is part of the Channel Control Structure and is used to specify the destination address for a  $\mu$ DMA transfer.

**Note:** The offset specified is from the base address of the control structure in system memory, not the  $\mu$ DMA module base address.

DMA Channel Destination Address End Pointer (DMADSTENDP)

|           |      |      |       | This field points to the last address of the $\mu$ DMA transfer destination (inclusive). If the destination address is not incrementing (the DSTINC field in the <b>DMACHCTL</b> register is 0x3), then this field points at the destination location itself (such as a peripheral data register). |

**Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008**

**DMA Channel Control Word (DMACHCTL)** is part of the Channel Control Structure and is used to specify parameters of a μDMA transfer.

**Note:** The offset specified is from the base address of the control structure in system memory, not the μDMA module base address.

**DMA Channel Control Word (DMACHCTL)**

| 13:4      | XFERSIZE                            | R/W  | -     | <p>Transfer Size (minus 1)</p> <p>This field configures the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items.</p> <p>The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer.</p> <p>The μDMA controller updates this field immediately prior to entering the arbitration process, so it contains the number of outstanding items that is necessary to complete the μDMA cycle.</p>                                                                                                                                                                                                                                                                                                                          |       |             |     |            |  |                                     |     |             |     |             |     |             |     |              |     |              |     |              |     |               |     |               |     |               |         |                |
| 3         | NXTUSEBURST                         | R/W  | -     | <p>Next Useburst</p> <p>This field controls whether the Useburst SET[n] bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the μDMA controller uses single transfers to complete the transaction. If this bit is set, then the controller uses a burst transfer to complete the last transfer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |             |     |            |  |                                     |     |             |     |             |     |             |     |              |     |              |     |              |     |               |     |               |     |               |         |                |

#### **XFERMODE Bit Field Values.**

##### **Stop**

Channel is stopped or configuration data is invalid. No more transfers can occur.

##### **Basic**

For each trigger (whether from a peripheral or a software request), the μDMA controller performs the number of transfers specified by the ARBSIZE field.

##### **Auto-Request**

The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of XFERSIZE items without any further requests.

##### **Ping-Pong**

This mode uses both the primary and alternate control structures for this channel. When the number of transfers specified by the XFERSIZE field have completed for the current control structure (primary or alternate), the μDMA controller switches to the other one. These switches continue until one of the control structures is not set to ping-pong mode. At that point, the μDMA controller stops. An interrupt is generated on completion of the transfers configured by each control structure. See “Ping-Pong” on page 247.

##### **Memory Scatter-Gather**

When using this mode, the primary control structure for the channel is configured to allow a list of operations (tasks) to be performed. The source address pointer specifies the start of a table of tasks to be copied to the alternate control structure for this channel. The XFERMODE field for the alternate control structure should be configured to 0x5 (Alternate memory scatter-gather) to perform the task. When the task completes, the μDMA switches back to the primary channel control structure, which then copies the next task to the alternate control structure. This process continues until the table of tasks is empty. The last task must have an XFERMODE value other than 0x5. Note that for continuous operation, the last task can update the primary channel control structure back to the start of the list or to another list. See “Memory Scatter-Gather” on page 248.

**Alternate Memory Scatter-Gather**

This value must be used in the alternate channel control data structure when the μDMA controller operates in Memory Scatter-Gather mode.

**Peripheral Scatter-Gather**

This value must be used in the primary channel control data structure when the μDMA controller operates in Peripheral Scatter-Gather mode. In this mode, the μDMA controller operates exactly the same as in Memory Scatter-Gather mode, except that instead of performing the number of transfers specified by the XFERSIZE field in the alternate control structure at one time, the μDMA controller only performs the number of transfers specified by the ARBSIZE field per trigger; see Basic mode for details. See “Peripheral Scatter-Gather” on page 252.

**Alternate Peripheral Scatter-Gather**

This value must be used in the alternate channel control data structure when the μDMA controller operates in Peripheral Scatter-Gather mode.

## **8.6 μDMA Register Descriptions**

The register addresses given are relative to the μDMA base address of 0x400F.F000.

## Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the  $\mu$ DMA controller. You cannot read this register when the  $\mu$ DMA controller is in the reset state.

### DMA Status (DMASTAT)

Base 0x400F.F000

Offset 0x000

Type RO, reset 0x001F.0000

Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that must be assigned to the μDMA controller depends on the number of μDMA channels used and whether the alternate channel control data structure is used. See “Channel Configuration” on page 245 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. This register cannot be read when the μDMA controller is in the reset state.

DMA Channel Control Base Pointer (DMACTLBASE)

Base 0x400F.F000  
Offset 0x008  
Type R/W, reset 0x0000.0000

| 9:0       | reserved | RO   | 0x00      | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

DMA Alternate Channel Control Base Pointer (DMAALTBASE)

|           |      |      |             | This field provides the base address of the alternate channel control structures. |

**Register 8: DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010**

This read-only register indicates that the μDMA channel is waiting on a request. A peripheral can hold off the μDMA from performing a single request until the peripheral is ready for a burst request to enhance the μDMA performance. The use of this feature is dependent on the design of the peripheral and is not controllable by software in any way. This register cannot be read when the μDMA controller is in the reset state.

Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding  $\mu$ DMA channel. Setting a bit generates a request for the specified  $\mu$ DMA channel.

**Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018**

Each bit of the **DMAUSEBURSTSET** register represents the corresponding  $\mu$ DMA channel. Setting a bit disables the channel's single request input from generating requests, configuring the channel to only accept burst requests. Reading the register returns the status of USEBURST.

If the amount of data to transfer is a multiple of the arbitration (burst) size, the corresponding SET[n] bit is cleared after completing the final transfer. If there are fewer items remaining to transfer than the arbitration (burst) size, the  $\mu$ DMA controller automatically clears the corresponding SET[n] bit, allowing the remaining items to transfer using single requests. In order to resume transfers using burst requests, the corresponding bit must be set again. A bit should not be set if the corresponding peripheral does not support the burst request model.

Refer to "Request Types" on page 244 for more details about request types.

| 1     | Setting a bit clears the corresponding SET[n] bit in the <b>DMAUSEBURSTSET</b> register meaning that $\mu$ DMA channel [n] responds to single and burst requests. |

Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding μDMA channel. Setting a bit disables μDMA requests for the channel. Reading the register returns the request mask status. When a μDMA channel's request is masked, that means the peripheral can no longer request μDMA transfers. The channel can then be used for software-initiated transfers.

## Value Description

0 No effect.

1 Setting a bit clears the corresponding SET[n] bit in the **DMAENASET** register meaning that channel [n] is disabled for  $\mu$ DMA transfers.

**Note:** The controller disables a channel when it completes the  $\mu$ DMA cycle.

**Register 16: DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030**

Each bit of the **DMAALTSET** register represents the corresponding μDMA channel. Setting a bit configures the μDMA channel to use the alternate control data structure. Reading the register returns the status of which control data structure is in use for the corresponding μDMA channel.

|-----------|--------|------|-------------|---------------------------|
| 31:0      | SET[n] | R/W  | 0x0000.0000 | Channel [n] Alternate Set |

**Value Description**

- 0 μDMA channel [n] is using the primary control structure.  
1 μDMA channel [n] is using the alternate control structure.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAALTCLR** register.

**Note:** For Ping-Pong and Scatter-Gather cycle types, the μDMA controller automatically sets these bits to select the alternate channel control data structure.

Register 17: DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034

Each bit of the **DMAALTCLR** register represents the corresponding  $\mu$ DMA channel. Setting a bit clears the corresponding SET[n] bit in the **DMAALTSET** register.

| 1     | Setting a bit clears the corresponding SET[n] bit in the <b>DMAALTSET</b> register meaning that channel [n] is using the primary control structure. |

**Note:** For Ping-Pong and Scatter-Gather cycle types, the  $\mu$ DMA controller automatically sets these bits to select the alternate channel control data structure.

Register 18: DMA Channel Priority Set (DMAPRIOSET), offset 0x038

Each bit of the **DMAPRIOSET** register represents the corresponding μDMA channel. Setting a bit configures the μDMA channel to have a high priority level. Reading the register returns the status of the channel priority mask.

| 31:0      | CLR[n] | WO   | -     | Channel [n] Priority Clear |

## Value Description

0 No effect.

1 Setting a bit clears the corresponding SET[n] bit in the **DMAPRIOSET** register meaning that channel [n] is using the default priority level.

Register 20: DMA Bus Error Clear (DMAERRCLR), offset 0x04C

The **DMAERRCLR** register is used to read and clear the μDMA bus error status. The error status is set if the μDMA controller encountered a bus error while performing a transfer. If a bus error occurs on a channel, that channel is automatically disabled by the μDMA controller. The other channels are unaffected.

## 9 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of nine physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F, Port G, Port H, Port J). The GPIO module supports up to 72 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Up to 72 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant input/outputs
- Fast toggle capable of a change every two clock cycles
- Two means of port access: either Advanced High-Performance Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables

### 9.1 Signal Description

GPIO signals have alternate hardware functions. Table 9-2 on page 300 and Table 9-3 on page 302 list the GPIO pins and their analog and digital alternate functions. The AINx and VREFA analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry (C0-,

C0+, C1-, C1+, C2-, C2+, USB0VBUS, USB0ID). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital alternate hardware functions are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMCx bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

Table 9-1. GPIO Pins With Non-Zero Reset Values

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|

a. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin.

## 9.2 Functional Description

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 9-1 on page 305 and Figure 9-2 on page 306). The LM3S5791 microcontroller contains nine ports and thus nine of these physical GPIO blocks. Note that not all pins may be implemented on every block. Some GPIO pins can function as I/O signals for the on-chip peripheral modules. For information on which GPIO pins are used for alternate hardware functions, refer to Table 24-5 on page 1099.

Figure 9-1. Digital I/O Pads

Figure 9-2. Analog/Digital I/O Pads

### 9.2.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

**Caution** – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

#### 9.2.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 315) is used to configure each individual pin as an input or output. When the data direction bit is cleared, the GPIO is configured as an input, and the corresponding data register bit captures and stores the value on the GPIO port. When the data direction bit is set, the GPIO is configured as an output, and the corresponding data register bit is driven out on the GPIO port.

### 9.2.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 314) by using bits [9:2] of the address bus as a mask. In this manner, software drivers can modify individual GPIO pins in a single instruction without affecting the state of the other pins. This method is more efficient than the conventional method of performing a read-modify-write operation to set or clear an individual GPIO pin. To implement this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address GPIODATA + 0x098 has the results shown in Figure 9-3, where u indicates that data is unchanged by the write.

**Figure 9-3. GPIODATA Write Example**

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 9-4.

**Figure 9-4. GPIODATA Read Example**

## 9.2.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. These registers are used to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, the external source must hold the level constant for the interrupt to be recognized by the controller.

Three registers define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 316)

- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 317)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 318)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 319).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 320 and page 321). As the name implies, the **GPIOMIS** register only shows interrupt conditions that are allowed to be passed to the interrupt controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the interrupt controller.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), an interrupt for Port B is generated, and an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 533.

If no other Port B pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETENA) register can disable the Port B interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the Port B interrupt handler must ignore and clear interrupts on PB4 and wait for the ADC interrupt, or the ADC interrupt must be disabled in the SETENA register and the Port B interrupt handler must poll the ADC registers until the conversion is completed. See the *ARM® Cortex™-M3 Technical Reference Manual* for more information.

Interrupts are cleared by writing a 1 to the appropriate bit of the **GPIO Interrupt Clear (GPIOICR)** register (see page 323).

When programming the interrupt control registers (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**), the interrupts should be masked (**GPIOIM** cleared). Writing any value to an interrupt control register can generate a spurious interrupt if the corresponding bits are enabled.

### 9.2.3 Mode Control

The GPIO pins can be controlled by either software or hardware. Software control is the default for most signals and corresponds to the GPIO mode, where the **GPIO DATA** register is used to read or write the corresponding pins. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), the pin state is controlled by its alternate function (that is, the peripheral).

Further pin muxing options are provided through the **GPIO Port Control (GPIOCTL)** register which selects one of several peripheral functions for each GPIO. For information on the configuration options, refer to Table 24-5 on page 1099.

**Note:** If any pin is to be used as an ADC input, the appropriate bit in the **GPIOAMSEL** register must be set to disable the analog isolation circuit.

### 9.2.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register

(see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

### 9.2.5 Pad Control

The pad control registers allow software to configure the GPIO pads based on the application requirements. The pad control registers include the **GPIOCR2R**, **GPIOCR4R**, **GPIOCR8R**, **GPIOODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GPIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable for each GPIO.

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package or BGA pin group with the total number of high-current GPIO outputs not exceeding four for the entire package.

### 9.2.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GPIOPeriphID7** registers as well as the **GPIOCellID0-GPIOCellID3** registers.

## 9.3 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris® parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHBCTL** register (see page 133).

To use the pins in a particular GPIO port, the clock for the port must be enabled by setting the appropriate GPIO Port bit field (GPIO $n$ ) in the **RCGC2** register (see page 191).

On reset, all GPIO pins are configured out of reset to be undriven (tristate): **GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0, except for the pins shown in Table 9-1 on page 300. Table 9-4 on page 309 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 9-5 on page 310 shows how a rising edge interrupt is configured for pin 2 of a GPIO port.

**Table 9-4. GPIO Pad Configuration Examples**

| Configuration                              | GPIO Register Bit Value <sup>a</sup> |     |     |     |     |     |      |      |      |     |
|--------------------------------------------|--------------------------------------|-----|-----|-----|-----|-----|------|------|------|-----|
|                                            | AFSEL                                | DIR | ODR | DEN | PUR | PDR | DR2R | DR4R | DR8R | SLR |

a. X=Ignored (don't care bit)

## 9.4 Register Map

Table 9-7 on page 312 lists the GPIO registers. Each GPIO port can be accessed through one of two bus apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris® parts. The other aperture, the Advanced High-Performance Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus.

**Important:** The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those

cases, writing to unconnected bits has no effect, and reading unconnected bits returns no meaningful data.

The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (APB): 0x4000.4000
- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (APB): 0x4000.5000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (APB): 0x4000.6000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (APB): 0x4000.7000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (APB): 0x4002.4000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (APB): 0x4002.5000
- GPIO Port F (AHB): 0x4005.D000
- GPIO Port G (APB): 0x4002.6000
- GPIO Port G (AHB): 0x4005.E000
- GPIO Port H (APB): 0x4002.7000
- GPIO Port H (AHB): 0x4005.F000
- GPIO Port J (APB): 0x4003.D000
- GPIO Port J (AHB): 0x4006.0000

Note that each GPIO module clock must be enabled before the registers can be programmed (see page 191).

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-6. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 1         | 1       | 0       | 0       | 0x1      |
| PB[3:2]   | I <sup>2</sup> C0 | 1         | 1       | 0       | 0       | 0x1      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x3      |

**Note:** The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins (PB7 and PC[3:0]). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins (PB7 and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the NMI pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset

value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of GPIOCR for Port C is 0x0000.00F0.

**Table 9-7. GPIO Register Map**

| Offset | Name          | Type | Reset       | Description                      | See page |
|--------|---------------|------|-------------|----------------------------------|----------|
| 0x000  | GPIODATA      | R/W  | 0x0000.0000 | GPIO Data                        | 314      |
| 0x400  | GPIODIR       | R/W  | 0x0000.0000 | GPIO Direction                   | 315      |
| 0x404  | GPIOIS        | R/W  | 0x0000.0000 | GPIO Interrupt Sense             | 316      |
| 0x408  | GPIOIBE       | R/W  | 0x0000.0000 | GPIO Interrupt Both Edges        | 317      |
| 0x40C  | GPIOIEV       | R/W  | 0x0000.0000 | GPIO Interrupt Event             | 318      |
| 0x410  | GPIOIM        | R/W  | 0x0000.0000 | GPIO Interrupt Mask              | 319      |

## 9.5 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

**Register 1: GPIO Data (GPIODATA), offset 0x000**

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 315).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be set. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are set in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are clear in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

**GPIO Data (GPIODATA)**

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000

| 7:0       | DATA     | R/W  | 0x00      | GPIO Data                                                                                                                                                                                     |

This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs. See "Data Register Operation" on page 307 for examples of reads and writes.

## Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Setting a bit in the **GPIODIR** register configures the corresponding pin to be an output, while clearing a bit configures the corresponding pin to be an input. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

**Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404**

The **GPIOIS** register is the interrupt sense register. Setting a bit in the **GPIOIS** register configures the corresponding pin to detect levels, while clearing a bit configures the corresponding pin to detect edges. All bits are cleared by a reset.

**GPIO Interrupt Sense (GPIOIS)**

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000

## Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register allows both edges to cause interrupts. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 316) is set to detect edges, setting a bit in the **GPIOIBE** register configures the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 318). Clearing a bit configures the pin to be controlled by the **GPIOIEV** register. All bits are cleared by a reset.

#### Value Description

- |   |                                                                                                          |
|---|----------------------------------------------------------------------------------------------------------|
| 0 | Interrupt generation is controlled by the <b>GPIO Interrupt Event (GPIOIEV)</b> register (see page 318). |
| 1 | Both edges on the corresponding pin trigger an interrupt.                                                |

**Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C**

The **GPIOIEV** register is the interrupt event register. Setting a bit in the **GPIOIEV** register configures the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 316). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in the **GPIOIS** register. All bits are cleared by a reset.

**Value Description**

|   |                                                                               |
|---|-------------------------------------------------------------------------------|
| 0 | A falling edge or a Low level on the corresponding pin triggers an interrupt. |
| 1 | A rising edge or a High level on the corresponding pin triggers an interrupt. |

## Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Setting a bit in the **GPIOIM** register allows interrupts that are generated by the corresponding pin to be sent to the interrupt controller on the combined interrupt signal. Clearing a bit prevents an interrupt on the corresponding pin from being sent to the interrupt controller. All bits are cleared by a reset.

#### Value Description

|   |                                                                               |
|---|-------------------------------------------------------------------------------|
| 0 | The interrupt from the corresponding pin is masked.                           |
| 1 | The interrupt from the corresponding pin is sent to the interrupt controller. |

## Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. A bit in this register is set when an interrupt condition occurs on the corresponding GPIO pin. If the corresponding bit in the **GPIO Interrupt Mask (GPIOIM)** register (see page 319) is set, the interrupt is sent to the interrupt controller. Bits read as zero indicate that corresponding input pins have not initiated an interrupt. A bit in this register can be cleared by writing a 1 to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register.

#### Value Description

|   |                                                                   |
|---|-------------------------------------------------------------------|
| 1 | An interrupt condition has occurred on the corresponding pin.     |
| 0 | An interrupt condition has not occurred on the corresponding pin. |

A bit is cleared by writing a 1 to the corresponding bit in the **GPIOICR** register.

## Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. If a bit is set in this register, the corresponding interrupt has triggered an interrupt to the interrupt controller. If a bit is clear, either no interrupt has been generated, or the interrupt is masked.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (the appropriate bit of GPIOIM is set), an interrupt for Port B is generated, and an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 533.

If no other Port B pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the Port B interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the Port B interrupt handler must ignore and clear interrupts on PB4 and wait for the ADC interrupt, or the ADC interrupt must be disabled in the SETNA register and the Port B interrupt handler must poll the ADC registers until the conversion is completed. See the *ARM® Cortex™-M3 Technical Reference Manual* for more information.

**GPIOMIS** is the state of the interrupt after masking.

## Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C

The **GPIOICR** register is the interrupt clear register. Writing a 1 to a bit in this register clears the corresponding interrupt bit in the **GPIOIRIS** and **GPIOMIS** registers. Writing a 0 has no effect.

### GPIO Interrupt Clear (GPIOICR)

**Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420**

The **GPIOAFSEL** register is the mode control select register. If a bit is clear, the pin is used as a GPIO and is controlled by the GPIO registers. Setting a bit in this register configures the corresponding GPIO line to be controlled by an associated peripheral. Several possible peripheral functions are multiplexed on each GPIO. The **GPIO Port Control (GPIOPCTL)** register is used to select one of the possible functions. Table 24-5 on page 1099 details which functions are muxed on each GPIO pin. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-8. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 1         | 1       | 0       | 0       | 0x1      |
| PB[3:2]   | I <sup>2</sup> C0 | 1         | 1       | 0       | 0       | 0x1      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x3      |

**Caution** – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris<sup>®</sup> microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

When using the I<sup>2</sup>C module, in addition to setting the **GPIOAFSEL** register bits for the I<sup>2</sup>C clock and data pins, the pins should be set to open drain using the **GPIO Open Drain Select (GPIODR)** register (see examples in “Initialization and Configuration” on page 309).

## Value Description

- 0 The associated pin functions as a GPIO and is controlled by the GPIO registers.
- 1 The associated pin functions as a peripheral signal and is controlled by the alternate hardware function.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 300.

**Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500**

The **GPIODR2R** register is the 2-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the DRV2 bit for a GPIO signal, the corresponding DRV4 bit in the **GPIODR4R** register and DRV8 bit in the **GPIODR8R** register are automatically cleared by hardware. By default, all GPIO pins have 2-mA drive.

**Value Description**

|   |                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------|
| 1 | The corresponding GPIO pin has 2-mA drive.                                                                 |
| 0 | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR4R</b> or <b>GPIODR8R</b> register. |

Setting a bit in either the **GPIODR4** register or the **GPIODR8** register clears the corresponding 2-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the DRV4 bit for a GPIO signal, the corresponding DRV2 bit in the **GPIODR2R** register and DRV8 bit in the **GPIODR8R** register are automatically cleared by hardware.

#### Value Description

- |   |                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------|
| 1 | The corresponding GPIO pin has 4-mA drive.                                                                 |
| 0 | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR2R</b> or <b>GPIODR8R</b> register. |

Setting a bit in either the **GPIODR2** register or the **GPIODR8** register clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

**Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508**

The **GPIODR8R** register is the 8-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the DRV8 bit for a GPIO signal, the corresponding DRV2 bit in the **GPIODR2R** register and DRV4 bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

**Note:** There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the  $V_{OH}/V_{OL}$  levels. See “Recommended DC Operating Conditions” on page 1145 for further information.

**Value Description**

- |   |                                                                                                            |
|---|------------------------------------------------------------------------------------------------------------|
| 1 | The corresponding GPIO pin has 8-mA drive.                                                                 |
| 0 | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR2R</b> or <b>GPIODR4R</b> register. |

Setting a bit in either the **GPIODR2** register or the **GPIODR4** register clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 14: GPIO Open Drain Select (GPIODR), offset 0x50C

The **GPIODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Input Enable (GPIODEN)** register (see page 335). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an open-drain input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I<sup>2</sup>C module, in addition to configuring the pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I<sup>2</sup>C clock and data pins should be set (see examples in “Initialization and Configuration” on page 309).

**Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510**

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 332). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-9. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 1         | 1       | 0       | 0       | 0x1      |
| PB[3:2]   | I <sup>2</sup> C0 | 1         | 1       | 0       | 0       | 0x1      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x3      |

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

## Value Description

|   |                                                    |
|---|----------------------------------------------------|
| 1 | The corresponding pin has a weak pull-up resistor. |
| 0 | The corresponding pin is not affected.             |

Setting a bit in the **GPIOPDR** register clears the corresponding bit in the **GPIOPUR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 300.

**Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514**

The **GPIOPDR** register is the pull-down control register. When a bit is set, a weak pull-down resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 330).

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-10. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 1         | 1       | 0       | 0       | 0x1      |
| PB[3:2]   | I <sup>2</sup> C0 | 1         | 1       | 0       | 0       | 0x1      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x3      |

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle. |

**Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518**

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA drive strength option via the **GPIO 8-mA Drive Select (GPIODR8R)** register (see page 328).

**GPIO Slew Rate Control Select (GPIOSLR)**

## Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

**Note:** Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, all GPIO signals except those listed below are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin as a digital input or output (either GPIO or alternate function), the corresponding GPIODEN bit must be set.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-11. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |
| PA[5:2]   | SSI0              | 1         | 1       | 0       | 0       | 0x1      |
| PB[3:2]   | I <sup>2</sup> C0 | 1         | 1       | 0       | 0       | 0x1      |
| PC[3:0]   | JTAG/SWD          | 1         | 1       | 0       | 1       | 0x3      |

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin (PB7) and the four JTAG/SWD pins (PC[3:0]). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 324), **GPIO Pull Up Select (GPIOPUR)** register (see page 330), **GPIO Pull-Down Select (GPIOPDR)** register (see page 332), and **GPIO Digital Enable (GPIODEN)** register (see page 335) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 337) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 338) have been set.

| 1                                                                                                             | The digital functions for the corresponding pin are enabled.  |
| The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 300. |                                                               |

## Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 338). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

### GPIO Lock (GPIOLOCK)

 Offset 0x520  
 Type R/W, reset 0x0000.0001

| Bit/Field | Name | Type | Reset       | Description |
|-----------|------|------|-------------|-------------|
| 31:0      | LOCK | R/W  | 0x0000.0001 | GPIO Lock   |

A write of the value 0x4C4F.434B unlocks the **GPIO Commit (GPIOCR)** register for write access. A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates.

A read of this register returns the following values:

| Value       | Description                                                   |
|-------------|---------------------------------------------------------------|
| 0x0000.0001 | The <b>GPIOCR</b> register is locked and may not be modified. |
| 0x0000.0000 | The <b>GPIOCR</b> register is unlocked and may be modified.   |

**Register 20: GPIO Commit (GPIOCR), offset 0x524**

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GPIONEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIONEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIONEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

**Important:** This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for PB7 and PC[3:0], the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins on PB7 and PC[3:0], all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIONEN** register bits of these other pins.

|           |          |      |           | 1 The corresponding <b>GPIOAFSEL</b> , <b>GPIOPUR</b> , <b>GPIOPDR</b> , or <b>GPIDEN</b> bits can be written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|           |          |      |           | 0 The corresponding <b>GPIOAFSEL</b> , <b>GPIOPUR</b> , <b>GPIOPDR</b> , or <b>GPIDEN</b> bits cannot be written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|           |          |      |           | <b>Note:</b> The default register type for the <b>GPIOCR</b> register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins (PB7 and PC[3:0]). These five pins are currently the only GPIOs that are protected by the <b>GPIOCR</b> register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.                                                                                                                                                                                                                               |
|           |          |      |           | The default reset value for the <b>GPIOCR</b> register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins (PB7 and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the NMI pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of <b>GPIOCR</b> for GPIO Port B is 0x0000.007F while the default reset value of <b>GPIOCR</b> for Port C is 0x0000.00F0. |

**Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528**

**Important:** This register is only valid for ports D and E; the corresponding base addresses for the remaining ports are not valid.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 24-5 on page 1099.

**Register 22: GPIO Port Control (GPIOPCTL), offset 0x52C**

The **GPIOPCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared on reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOPCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the defined encodings for the bit fields in this register, refer to Table 24-5 on page 1099. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0) with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 9-12. GPIO Pins With Non-Zero Reset Values**

| GPIO Pins | Default State     | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL |
|-----------|-------------------|-----------|---------|---------|---------|----------|
| PA[1:0]   | UART0             | 1         | 1       | 0       | 0       | 0x1      |

## 10 External Peripheral Interface (EPI)

The External Peripheral Interface is a high-speed parallel bus for external peripherals or memory. It has several modes of operation to interface gluelessly to many types of external devices. The External Peripheral Interface is similar to a standard microprocessor address/data bus, except that it must typically be connected to just one type of external device. Enhanced capabilities include  $\mu$ DMA support, clocking control and support for external FIFO buffers.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal non-blocking read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM)
  - Supports x16 (single data rate) SDRAM at up to 50 MHz
  - Supports low-cost SDRAMs up to 64 MB (512 megabits)
  - Includes automatic refresh and access to all banks/rows
  - Includes a Sleep/Standby mode to keep contents active with minimal power draw
  - Multiplexed address/data interface for reduced pin count
- Host-bus
  - Traditional x8 and x16 MCU bus interface capabilities
  - Similar device compatibility options as PIC, ATmega, 8051, and others
  - Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in unmultiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)

- Support of both muxed and de-muxed address and data
- Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
- Speed controlled, with read and write data wait-state counters
- Chip select modes include ALE, CSn, Dual CSn and ALE with dual CSn
- Manual chip-enable (or use extra address pins)
- General Purpose
  - Wide parallel interfaces for fast communications with CPLDs and FPGAs
  - Data widths up to 32-bits
  - Data rates up to 150 MB/second
  - Optional “address” sizes from 4 bits to 20 bits
  - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
  - 1 to 32 bits, FIFOed with speed control
  - Useful for custom peripherals or for digital data acquisition and actuator controls

## 10.1 EPI Block Diagram

Figure 10-1 on page 358 provides a block diagram of a Stellaris® EPI module.

Figure 10-1. EPI Block Diagram

## 10.2 Signal Description

Table 10-1 on page 358 and Table 10-2 on page 359 list the external signals of the EPI controller and describe the function of each. The EPI controller signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the EPI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 324) should be set to choose the EPI controller function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 342) to assign the EPI signals to the specified GPIO port pins. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 299.

## 10.3 Functional Description

The EPI controller provides a glueless, programmable interface to a variety of common external peripherals such as SDRAM, Host Bus x8 and x16 devices, RAM, NOR Flash memory, CPLDs and FPGAs. In addition, the EPI controller provides custom GPIO that can use a FIFO with speed control by using either the internal write FIFO (WFIFO) or the non-blocking read FIFO (NBRFIFO). The WFIFO can hold 4 words of data that are written to the external interface at the rate controlled by the **EPI Main Baud Rate (EPIBAUD)** register. The NBRFIFO can hold 8 words of data and samples at the rate controlled by the **EPIBAUD** register. The EPI controller provides predictable operation and thus has an advantage over regular GPIO which has more variable timing due to on-chip bus arbitration and delays across bus bridges. Blocking reads stall the CPU until the transaction completes. Non-blocking reads are performed in the background and allow the processor to continue operation. In addition, write data can also be stored in the WFIFO to allow multiple writes with no stalls.

Main read and write operations can be performed in subsets of the range 0x6000.0000 to 0xDFFF.FFFF. A read from an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value load, the read is done as a burst (when available) to maximize performance. A write to an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value store, the write is done as a burst (when available) to maximize performance.

NAND Flash memory (x8) can be read natively. Automatic programming support is not provided; programming must be done by the user following the manufacturer's protocol. Automatic page ECC is also not supported, but can be performed in software.

### 10.3.1 Non-Blocking Reads

The EPI Controller supports a special kind of read called a non-blocking read, also referred to as a posted read. Where a normal read stalls the processor or  $\mu$ DMA until the data is returned, a non-blocking read is performed in the background.

A non-blocking read is configured by writing the start address into a **EPIRADDRn** register, the size per transaction into a **EPIRSIZEn** register, and then the count of operations into a **EPIRPSTDn** register. After each read is completed, the result is written into the NBRFIFO and the **EPIRADDRn** register is incremented by the size (1, 2, or 4).

If the NBRFIFO is filled, then the reads pause until space is made available. The NBRFIFO can be configured to interrupt the processor or trigger the  $\mu$ DMA based on fullness using the **EPIFIFOLVL** register. By using the trigger/interrupt method, the  $\mu$ DMA (or processor) can keep space available in the NBRFIFO and allow the reads to continue unimpeded.

When performing non-blocking reads, the SDRAM controller issues two additional read transactions after the burst request is terminated. The data for these additional transfers is discarded. This situation is transparent to the user other than the additional EPI bus activity and can safely be ignored.

Two non-blocking read register sets are available to allow sequencing and ping-pong use. When one completes, the other then activates. So, for example, if 20 words are to be read from 0x100 and 10 words from 0x200, the **EPIRPSTD0** register can be set up with the read from 0x100 (with a count of 20), and the **EPIRPSTD1** register can be set up with the read from 0x200 (with a count of 10). When **EPIRPSTD0** finishes (count goes to 0), the **EPIRPSTD1** register then starts its operation. The NBRFIFO has then passed 30 values. When used with the  $\mu$ DMA, it may transfer 30 values (simple sequence), or the primary/alternate model may be used to handle the first 20 in one way and the second 10 in another. It is also possible to reload the **EPIRPSTD0** register when it is finished (and the **EPIRPSTD1** register is active); thereby, keeping the interface constantly busy.

To cancel a non-blocking read, the **EPIRPSTDn** register is cleared. Care must be taken, however if the register set was active to drain away any values read into the NBRFIFO and ensure that any read in progress is allowed to complete.

To ensure that the cancel is complete, the following algorithm is used (using the **EPIRPSTD0** register for example):

```
EPIRPSTD0 = 0;
while ((EPISTAT & 0x11) == 0x10)
; // we are active and busy
// if here, then other one is active or interface no longer busy
cnt = (EPIRADDR0 – original_address) / EPIRSIZE0; // count of values read
```

```
cnt -= values_read_so_far;
// cnt is now number left in FIFO
while (cnt--)
value = EPIREADFIFO; // drain
```

The above algorithm can be optimized in code; however, the important point is to wait for the cancel to complete because the external interface could have been in the process of reading a value when the cancel came in, and it must be allowed to complete.

### 10.3.2 DMA Operation

The  $\mu$ DMA can be used to efficiently transfer data from and to the NBRFIFO and the WFIFO. The  $\mu$ DMA has one channel for write and one for read. The write channel copies values to the WFIFO when the WFIFO is at the level specified by the **EPI FIFO Level Selects (EPIFIFOLVL)** register. The non-blocking read channel copies values from the NBRFIFO when the NBRFIFO is at the level specified by the **EPIFIFOLVL** register. For non-blocking reads, the start address, the size per transaction, and the count of elements must be programmed in the  $\mu$ DMA. Note that both non-blocking read register sets can be used, and they fill the NBRFIFO such that one runs to completion, then the next one starts (they do not interleave).

For blocking reads, the  $\mu$ DMA software channel (or another unused channel) is used for memory-to-memory transfers (or memory to peripheral, where some other peripheral is used). In this situation, the  $\mu$ DMA stalls until the read is complete and is not able to service another channel until the read is done. As a result, the arbitration size should normally be programmed to one access at a time. The  $\mu$ DMA controller can also transfer from and to the NBRFIFO and the WFIFO using the  $\mu$ DMA software channel in memory mode, however, the  $\mu$ DMA is stalled once the NBRFIFO is empty or the WFIFO is full. Note that when the  $\mu$ DMA controller is stalled, the core continues operation. See "Micro Direct Memory Access ( $\mu$ DMA)" on page 241 for more information on configuring the  $\mu$ DMA.

## 10.4 Initialization and Configuration

To enable and initialize the EPI controller, the following steps are necessary:

1. Enable the EPI module using the **RCGC1** register. See page 179.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register. See page 191. To find out which GPIO port to enable, refer to Table 10-1 on page 358 or Table 10-2 on page 359.
3. Set the GPIO AFSEL bits for the appropriate pins. See page 324. To determine which GPIOs to configure, see Table 24-4 on page 1090.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected. See page 326 and page 334.
5. Configure the PMCn fields in the **GPIOPCTL** register to assign the EPI signals to the appropriate pins. See page 342 and Table 24-5 on page 1099.
6. Select the mode for the EPI block to SDRAM, HB8, HB16, or general parallel use, using the MODE field in the **EPI Configuration (EPICFG)** register. Set the mode-specific details (if needed) using the appropriate mode configuration **EPI xxx Configuration (EPIxxxCFG)** and **EPI xxx Configuration 2 (EPIxxxCFG2)** registers. Set the **EPI Main Baud Rate (EPIBAUD)** register if the baud rate must be slower than the system clock rate.

7. Configure the address mapping using the **EPI Address Map (EPIADDRMAP)** register. The selected start address and range is dependent on the type of external device and maximum address (as appropriate). For example, for a 512-megabit SDRAM, program the ERADR field to 0x1 for address 0x6000.0000 or 0x2 for address 0x8000.0000; and program the ERSZ field to 0x3 for 256 MB. If using General-Purpose mode and no address at all, program the EPADR field to 0x1 for address 0xA000.0000 or 0x2 for address 0xC000.0000; and program the EPSZ field to 0x0 for 256 bytes.
8. To read or write directly, use the mapped address area (configured with the **EPIADDRMAP** register). Up to 4 or 5 writes can be performed at once without blocking. Each read is blocked until the value is retrieved.
9. To perform a non-blocking read, see “Non-Blocking Reads” on page 361.

The following sub-sections describe the initialization and configuration for each of the modes of operation. Care must be taken to initialize everything properly to ensure correct operation. Control of the GPIO states is also important, as changes may cause the external device to interpret pin states as actions or commands (see “Register Descriptions” on page 313). Normally, a pull-up or pull-down is needed on the board to at least control the chip-select or chip-enable as the Stellaris® GPIOs come out of reset in tri-state.

#### 10.4.1 SDRAM Mode

When activating the SDRAM mode, it is important to consider a few points:

1. Generally, it takes over 100  $\mu$ s from when the mode is activated to when the first operation is allowed. The SDRAM controller begins the SDRAM initialization sequence as soon as the mode is selected and enabled via the **EPICFG** register. It is important that the GPIOs are properly configured before the SDRAM mode is enabled, as the EPI controller is relying on the GPIO block's ability to drive the pins immediately. As part of the initialization sequence, the LOAD MODE REGISTER command is automatically sent to the SDRAM with a value of 0x27, which sets a CAS latency of 2 and a full page burst length.
2. The INITSEQ bit in the **EPI Status (EPISTAT)** register can be checked to determine when the initialization sequence is complete.
3. When using a frequency range and/or refresh value other than the default value, it is important to configure the FREQ and RFSH fields in the **EPI SDRAM Configuration (EPISDRAMCFG)** register shortly after activating the mode. After the 100- $\mu$ s startup time, the EPI block must be configured properly to keep the SDRAM contents stable.
4. The SLEEP bit in the **EPISDRAMCFG** register may be configured to put the SDRAM into a low-power self-refreshing state. It is important to note that the SDRAM mode must not be disabled once enabled, or else the SDRAM is no longer clocked and the contents are lost.

The SIZE field of the **EPISDRAMCFG** register must be configured correctly based on the amount of SDRAM in the system.

The FREQ field must be configured according to the value that represents the range being used. Based on the range selected, the number of external clocks used between certain operations (for example, PRECHARGE or ACTIVATE) is determined. If a higher frequency is given than is used, then the only downside is that the peripheral is slower (uses more cycles for these delays). If a lower frequency is given, incorrect operation occurs.

See “External Peripheral Interface (EPI)” on page 1153 for timing details for the SDRAM mode.

### 10.4.1.1 External Signal Connections

Table 10-3 on page 364 defines how EPI module signals should be connected to SDRAMs. The table applies when using a x16 SDRAM up to 512 megabits. Note that the EPI signals must use 8-mA drive when interfacing to SDRAM, see page 328. Any unused EPI controller signals can be used as GPIOs or another alternate function.

**Table 10-3. EPI SDRAM Signal Connections**

| EPI Signal      | SDRAM Signal <sup>a</sup> |     |
|-----------------|---------------------------|-----|
| EPI0S0          | A0                        | D0  |
| EPI0S1          | A1                        | D1  |
| EPI0S2          | A2                        | D2  |
| EPI0S3          | A3                        | D3  |
| EPI0S4          | A4                        | D4  |
| EPI0S5          | A5                        | D5  |
| EPI0S6          | A6                        | D6  |
| EPI0S7          | A7                        | D7  |
| EPI0S8          | A8                        | D8  |
| EPI0S9          | A9                        | D9  |
| EPI0S10         | A10                       | D10 |
| EPI0S11         | A11                       | D11 |
| EPI0S12         | A12 <sup>b</sup>          | D12 |
| EPI0S13         | BA0                       | D13 |
| EPI0S14         | BA1                       | D14 |
| EPI0S15         | D15                       |     |
| EPI0S16         | DQML                      |     |
| EPI0S17         | DQMH                      |     |
| EPI0S18         | CASn                      |     |
| EPI0S19         | RASn                      |     |
| EPI0S20-EPI0S27 | not used                  |     |
| EPI0S28         | WEn                       |     |
| EPI0S29         | CSn                       |     |
| EPI0S30         | CKE                       |     |
| EPI0S31         | CLK                       |     |

a. If 2 signals are listed, connect the EPI signal to both pins.

b. Only for 256/512 megabit SDRAMs

### 10.4.1.2 Refresh Configuration

The refresh count is based on the external clock speed and the number of rows per bank as well as the refresh period. The RFSH field represents how many external clock cycles remain before an AUTO-REFRESH is required. The normal formula is:

$$\text{RFSH} = (\text{t}_{\text{Refresh\_us}} / \text{number\_rows}) / \text{ext\_clock\_period}$$

A refresh period is normally 64 ms, or 64000  $\mu\text{s}$ . The number of rows is normally 4096 or 8192. The ext\_clock\_period is a value expressed in  $\mu\text{sec}$  and is derived by dividing 1000 by the clock speed expressed in MHz. So, 50 MHz is  $1000/50=20$  ns, or 0.02  $\mu\text{s}$ . A typical SDRAM is 4096 rows per bank if the system clock is running at 50 MHz with an **EPIBAUD** register value of 0:

$$RFSH = (64000/4096) / 0.02 = 15.625 \mu s / 0.02 \mu s = 781.25$$

The default value in the RFSH field is 750 decimal or 0x2EE to allow for a margin of safety and providing 15  $\mu s$  per refresh. It is important to note that this number should always be smaller or equal to what is required by the above equation. For example, if running the external clock at 25 MHz (40 ns per clock period), 390 is the highest number that may be used. Note that the external clock may be 25 MHz when the system clock is 25 MHz or when the system clock is 50 MHz and configuring the COUNT0 field in the **EPIBAUD** register to 1 (divide by 2).

If a number larger than allowed is used, the SDRAM is not refreshed often enough, and data is lost.

#### 10.4.1.3 Bus Interface Speed

The EPI Controller SDRAM interface can operate up to 50 MHz. The COUNT0 field in the **EPIBAUD** register configures the speed of the EPI clock. For system clock (SysClk) speeds up to 50 MHz, the COUNT0 field can be 0x0000, and the SDRAM interface can run at the same speed as SysClk. However, if SysClk is running at higher speeds, the bus interface can run only as fast as half speed, and the COUNT0 field must be configured to at least 0x0001.

#### 10.4.1.4 Non-Blocking Read Cycle

Figure 10-2 on page 365 shows a non-blocking read cycle of n halfwords; n can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the EPI0S[15:0] signals. With the programmed CAS latency of 2, the Read command with the column address on the EPI0S[15:0] signals follows after 2 clock cycles. Following one more NOP cycle, data is read in on the EPI0S[15:0] signals on every rising clock edge. The Burst Terminate command is issued during the cycle when the next-to-last halfword is read in. The DQMH and DQML signals are deasserted after the last halfword of data is received; the CSn signal deasserts on the following clock cycle, signaling the end of the read cycle. At least one clock period of inactivity separates any two SDRAM cycles.

**Figure 10-2. SDRAM Non-Blocking Read Cycle**

#### 10.4.1.5 Normal Read Cycle

Figure 10-3 on page 366 shows a normal read cycle of n halfwords; n can be 1 or 2. The cycle begins with the Activate command and the row address on the EPI0S[15:0] signals. With the programmed CAS latency of 2, the Read command with the column address on the EPI0S[15:0] signals follows

after 2 clock cycles. Following one more NOP cycle, data is read in on the EPI0S[15:0] signals on every rising clock edge. The DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the cycle. At least one clock period of inactivity separates any two SDRAM cycles.

**Figure 10-3. SDRAM Normal Read Cycle**

#### 10.4.1.6 Write Cycle

Figure 10-4 on page 367 shows a write cycle of  $n$  halfwords;  $n$  can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the EPI0S[15:0] signals. With the programmed CAS latency of 2, the Write command with the column address on the EPI0S[15:0] signals follows after 2 clock cycles. When writing to SDRAMs, the Write command is presented with the first halfword of data. Because the address lines and the data lines are multiplexed, the column address is modified to be (programmed address -1). During the Write command, the DQMH and DQML signals are high, so no data is written to the SDRAM. On the next clock, the DQMH and DQML signals are asserted, and the data associated with the programmed address is written. The Burst Terminate command occurs during the clock cycle following the write of the last halfword of data. The WEn, DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the access. At least one clock period of inactivity separates any two SDRAM cycles.

**Figure 10-4. SDRAM Write Cycle**

## 10.4.2 Host Bus Mode

Host Bus supports the traditional 8-bit and 16-bit interfaces popularized by the 8051 devices and SRAM devices. This interface is asynchronous and uses strobe pins to control activity.

### 10.4.2.1 Control Pins

The main three strobes are ALE (Address latch enable), WRn (write), and RDn (sometimes called OEn, used for read). Note that the timings are designed for older logic and so are hold-time vs. setup-time specific. To ensure proper operation on this bus, the EPI block uses two system clocks per transition to allow significant skewing of control vs. data signals. So, for example, ALE rises one EPI clock before ADDR/DATA is asserted. Likewise, ALE falls (latch point) one EPI clock before DATA changes or tri-states. The same approach is used for the WRn and RDn/OEn strobes. The polarity of the read and write strobes can be active high or active low by clearing or setting the RDHIGH and WRHIGH bits in the **EPI Host-Bus n Configuration 2 (EPIHBnCFG2)** register.

The ALE can be changed to an active-low chip select signal, CSn, through the **EPIHBnCFG2** register. The ALE is best used for Host-Bus muxed mode in which EPI address and data pins are shared. All Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold it until the data phase. CSn is best used for Host-Bus unmuxed mode in which EPI address and data pins are separate. The CSn indicates when the address and data phases of a read or write access is occurring. Both the ALE and the CSn modes can be enhanced to access two external devices using settings in the **EPIHBnCFG2** register. Wait states can be added to the data phase of the access using the WRWS and RDWS bits in the **EPIHBnCFG2** register.

For FIFO mode, the ALE is not used, and two input holds are optionally supported to gate input and output to what the XFIFO can handle.

Host-Bus 8 and Host-Bus 16 modes are very configurable. The user has the ability to connect 1 or 2 external devices to the EPI signals as well as control whether byte select signals are provided in HB16 mode. These capabilities depend on the configuration of the MODE field in the **EPIHBnCFG** register, the CSCFG field in the **EPIHBnCFG2** register, and the BSEL bit in the **EPIHB16CFG** register.

If one of the Dual-Chip-Select modes is selected (CSCFG=0x2 or 0x3 in the **EPIHBnCFG2** register), both chip selects can share the peripheral or the memory space, or one chip select can use the peripheral space and the other can use the memory space. In the **EPIADDRMAP** register, if the EPADR field is not 0x0 and the ERADR field is 0x0, then the address specified by EPADR is used for both chip selects, with CS0n being asserted when the MSB of the address range is 0 and CS1n being asserted when the MSB of the address range is 1. If the ERADR field is not 0x0 and the EPADR field is 0x0, then the address specified by ERADR is used for both chip selects, with the MSB performing the same delineation. If both the EPADR and the ERADR are not 0x0, then CS0n is asserted for the address range defined by EPADR and CS1n is asserted for the address range defined by ERADR. If the CSBAUD bit in the **EPIHBnCFG2** register is set, the 2 chip selects can use different clock frequencies. If the CSBAUD bit is clear, both chip selects use the clock frequency, wait states, and strobe polarity defined for CS0n.

When BSEL=1 in the **EPIHB16CFG** register, byte select signals are provided, so byte-sized data can be read and written at any address, however these signals reduce the available address width by 2 pins. The byte select signals are active low. BSEL0n corresponds to the LSB of the halfword, and BSEL1n corresponds to the MSB of the halfword.

When BSEL=0, byte reads and writes at odd addresses only act on the even byte, and byte writes at even addresses write invalid values into the odd byte. As a result, accesses should be made as half-words (16-bits) or words (32-bits). In C/C++, programmers should use only short int and long int for accesses. Also, because data accesses in HB16 mode with no byte selects are on 2-byte boundaries, the available address space is doubled. For example, 28 bits of address accesses 512 MB in this mode. Table 10-4 on page 368 shows the capabilities of the HB8 and HB16 modes as well as the available address bits with the possible combinations of these bits.

Although the EPI0S31 signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system.

**Table 10-4. Capabilities of Host Bus 8 and Host Bus 16 Modes**

| Host Bus Type | MODE | CSCFG    | Max # of External Devices | BSEL | Byte Access | Available Address    |
|---------------|------|----------|---------------------------|------|-------------|----------------------|
| HB8           | 0x0  | 0x0, 0x1 | 1                         | N/A  | Always      | 28 bits              |
| HB8           | 0x0  | 0x2      | 2                         | N/A  | Always      | 27 bits              |
| HB8           | 0x0  | 0x3      | 2                         | N/A  | Always      | 26 bits              |
| HB8           | 0x1  | 0x0, 0x1 | 1                         | N/A  | Always      | 20 bits              |
| HB8           | 0x1  | 0x2      | 2                         | N/A  | Always      | 19 bits              |
| HB8           | 0x1  | 0x3      | 2                         | N/A  | Always      | 18 bits              |
| HB8           | 0x3  | 0x1      | 1                         | N/A  | Always      | none                 |
| HB8           | 0x3  | 0x3      | 2                         | N/A  | Always      | none                 |
| HB16          | 0x0  | 0x0, 0x1 | 1                         | 0    | No          | 28 bits <sup>a</sup> |
| HB16          | 0x0  | 0x0, 0x1 | 1                         | 1    | Yes         | 26 bits              |
| HB16          | 0x0  | 0x2      | 2                         | 0    | No          | 27 bits <sup>a</sup> |
| HB16          | 0x0  | 0x2      | 2                         | 1    | Yes         | 25 bits              |
| HB16          | 0x0  | 0x3      | 2                         | 0    | No          | 26 bits <sup>a</sup> |
| HB16          | 0x0  | 0x3      | 2                         | 1    | Yes         | 24 bits              |
| HB16          | 0x1  | 0x0, 0x1 | 1                         | 0    | No          | 12 bits <sup>a</sup> |
| HB16          | 0x1  | 0x0, 0x1 | 1                         | 1    | Yes         | 10 bits              |
| HB16          | 0x1  | 0x2      | 2                         | 0    | No          | 11 bits <sup>a</sup> |

**Table 10-4. Capabilities of Host Bus 8 and Host Bus 16 Modes (continued)**

| Host Bus Type | MODE | CSCFG | Max # of External Devices | BSEL | Byte Access | Available Address    |
|---------------|------|-------|---------------------------|------|-------------|----------------------|
| HB16          | 0x1  | 0x2   | 2                         | 1    | Yes         | 9 bits               |
| HB16          | 0x1  | 0x3   | 2                         | 0    | No          | 10 bits <sup>a</sup> |
| HB16          | 0x1  | 0x3   | 2                         | 1    | Yes         | 8 bits               |
| HB16          | 0x3  | 0x1   | 1                         | 0    | No          | none                 |
| HB16          | 0x3  | 0x1   | 1                         | 1    | Yes         | none                 |

| HB16          | 0x3  | 0x3   | 2                         | 1    | Yes         | none                 |

a. If byte selects are not used, data accesses are on 2-byte boundaries. As a result, the available address space is doubled.

Table 10-5 on page 369 shows how the EPI [31:0] signals function while in Host-Bus 8 mode. Notice that the signal configuration changes based on the address/data mode selected by the MODE field in the **EPIHB8CFG2** register and on the chip select configuration selected by the CSCFG field in the same register. Any unused EPI controller signals can be used as GPIOs or another alternate function.

**Table 10-5. EPI Host-Bus 8 Signal Connections**

| EPI Signal | CSCFG          | HB8 Signal (MODE =ADMUX) | HB8 Signal (MODE =ADNOMUX (Cont. Read)) | HB8 Signal (MODE =XFIFO) |
|------------|----------------|--------------------------|-----------------------------------------|--------------------------|

a. "X" indicates the state of this field is a don't care.

b. When an entry straddles several row, the signal configuration is the same for all rows.

c. The clock signal is not required for this mode and has unspecified timing relationships to other signals.

Table 10-6 on page 370 shows how the EPI [31:0] signals function while in Host-Bus 16 mode. Notice that the signal configuration changes based on the address/data mode selected by the MODE field in the **EPIHB16CFG2** register, on the chip select configuration selected by the CSCFG field in the same register, and on whether byte selects are used as configured by the BSEL bit in the **EPIHB16CFG** register. Any unused EPI controller signals can be used as GPIOs or another alternate function.

Table 10-6. EPI Host-Bus 16 Signal Connections

a. "X" indicates the state of this field is a don't care.

b. In this mode, half-word accesses are used. AO is the LSB of the address and is equivalent to the system A1 address.

c. When an entry straddles several row, the signal configuration is the same for all rows.

d. The clock signal is not required for this mode and has unspecified timing relationships to other signals.

### 10.4.2.2 Speed of Transactions

The COUNT0 field in the **EPIBAUD** register must be configured to set the main transaction rate based on what the slave device can support (including wiring considerations). The main control transitions are normally ½ the baud rate (COUNT0 = 1) because the EPI block forces data vs. control to change on alternating clocks. When using dual chip-selects, each chip select can access the bus using differing baud rates by setting the CSBAUD bit in the **EPIHBnCFG2** register. In this case, the COUNT0 field controls the CS0n transactions, and the COUNT1 field controls the CS1n transactions.

Additionally, the Host-Bus mode provides read and write wait states for the data portion to support different classes of device. These wait states stretch the data period (hold the rising edge of data strobe) and may be used in all four sub-modes. The wait states are set using the WRWS and RDWS bits in the **EPI Host-Bus n Configuration (EPIHBnCFG)** register.

### 10.4.2.3 Sub-Modes of Host Bus 8/16

The EPI controller supports four variants of the Host-Bus model using 8 or 16 bits of data in all four cases. The four sub-modes are selected using the MODE bits in the **EPIHBnCFG** register, and are:

1. Address and data are muxed. This scheme is used by many 8051 devices, some Microchip PIC parts, and some ATmega parts. When used for standard SRAMs, a latch must be used between the microcontroller and the SRAM. This sub-mode is provided for compatibility with existing devices that support data transfers without a latch (for example, LCD controllers or CPLDs). In general, the de-muxed sub-mode should normally be used. The ALE configuration should be used in this mode, as all Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold until the data phase. The ALE configuration is controlled by configuring the CSCFG field to be 0x0 in the **EPIHBnCFG2** register. The ALE can be enhanced to access two external devices with the addition of two separate CSn signals. By configuring the CSCFG field in the to be 0x3 in the **EPIHBnCFG2**

register, EPI0S30 functions as ALE, EPI0S27 functions as CS1n, and EPI0S26 functions as CS0n. The CSn is best used for Host-Bus unmuxed mode which EPI address and data pins are separate. The CSn indicates when the address and data phases of a read or write access are occurring.

2. Address and data are separate with 8 or 16 bits of data and up to 20 bits of address (1 MB). This scheme is used by more modern 8051 devices, as well as some PIC and ATmega parts. This mode is generally used with real SRAMs, many EEPROMs, and many NOR Flash memory devices. Note that there is no hardware command write support for Flash memory devices; this mode should only be used for Flash memory devices programmed at manufacturing time. If a Flash memory device must be written and does not support a direct programming model, the command mechanism must be performed in software. The CSn configuration should be used in this mode. The CSn signal indicates when the address and data phases of a read or write access is occurring. The CSn configuration is controlled by configuring the CSCFG field to be 0x1 in the **EPIHBnCFG2** register.
3. Continuous read mode where address and data are separate. This sub-mode is used for real SRAMs which can be read more quickly by only changing the address (and not using RDn/OEn strobing). In this sub-mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change. For example, to read data from address 0x100 and then 0x101, the EPI controller asserts the output-enable signal and then configures the address pins to 0x100; the EPI controller then captures what is on the data pins and increments A0 to 1 (so the address is now 0x101); the EPI controller then captures what is on the data pins. Note that this mode consumes higher power because the SRAM must continuously drive the data pins. This mode is not practical in HB16 mode for normal SRAMs because there are generally not enough address bits available.
4. FIFO mode uses 8 or 16 bits of data, removes ALE and address pins and optionally adds external XFIFO FULL/EMPTY flag inputs. This scheme is used by many devices, such as radios, communication devices (including USB2 devices), and some FPGA configurations (FIFO through block RAM). This sub-mode provides the data side of the normal Host-Bus interface, but is paced by the FIFO control signals. It is important to consider that the XFIFO FULL/EMPTY control signals may stall the interface and could have an impact on blocking read latency from the processor or  $\mu$ DMA.

The WORD bit in the **EPIHBnCFG2** register can be set to use memory more efficiently. By default, the EPI controller uses data bits [7:0] for Host-Bus 8 accesses or bits [15:0] for Host-Bus 16 accesses. When the WORD bit is set, the EPI controller can automatically route bytes of data onto the correct byte lanes such that data can be stored in bits [31:8] (HB8) or [31:16] (HB16). In addition, for the three modes above (1, 2, 4) that the Host-Bus 16 mode supports, byte select signals can be optionally implemented by setting the BSEL bit in the **EPIHB16CFG** register.

See "External Peripheral Interface (EPI)" on page 1153 for timing details for the Host-Bus mode.

#### 10.4.2.4 Bus Operation

Bus operation is the same in Host-Bus 8 and Host-Bus 16 modes and is asynchronous. Timing diagrams show both ALE and CSn operation, but only one signal or the other is used in all modes except for ALE with dual chip selects mode (CSCFG field is 0x3 in the **EPIHBnCFG2** register). Address and data on write cycles are held after the CSn signal is deasserted. The optional HB16 byte select signals have the same timing as the address signals. If wait states are required in the bus access, they can be inserted during the data phase of the access using the WRWS and RDWS

bits in the **EPIHBnCFG2** register. Each wait state adds 2 EPI clock cycles to the duration of the WRn or RDn strobe.

Figure 10-5 on page 374 shows a basic Host-Bus read cycle. Figure 10-6 on page 374 shows a basic Host-Bus write cycle. Both of these figures show address and data signals in the non-multiplexed mode (MODE field ix 0x1 in the **EPIHBnCFG** register).

**Figure 10-5. Host-Bus Read Cycle, MODE = 0x1, WRHIGH = 1, RDHIGH = 1**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

**Figure 10-6. Host-Bus Write Cycle, MODE = 0x1, WRHIGH = 1, RDHIGH = 1**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 10-7 on page 375 shows a write cycle with the address and data signals multiplexed (MODE field is 0x0 in the **EPIHBnCFG** register). A read cycle would look similar, with the RDn strobe being asserted along with CSn and data being latched on the rising edge of RDn.

**Figure 10-7. Host-Bus Write Cycle with Multiplexed Address and Data, MODE = 0x0, WRHIGH = 1, RDHIGH = 1**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 10-8 on page 375 shows continuous read mode accesses. In this mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change.

**Figure 10-8. Continuous Read Mode Accesses**

FIFO mode accesses are the same as normal read and write accesses, except that the ALE signal and address pins are not present. Two input signals can be used to indicate when the XFIFO is full or empty to gate transactions and avoid overruns and underruns. The FFULL and FEMPTY signals are synchronized and must be recognized as asserted by the microcontroller for 2 system clocks before they affect transaction status. The MAXWAIT field in the **EPIHBnCFG** register defines the maximum number of EPI clocks to wait while the FEMPTY or FFULL signal is holding off a transaction. Figure 10-9 on page 376 shows how the FEMPTY signal should respond to a write and read from the XFIFO. Figure 10-10 on page 376 shows how the FEMPTY and FFULL signals should respond to 2 writes and 1 read from an external FIFO that contains two entries.

**Figure 10-9. Write Followed by Read to External FIFO****Figure 10-10. Two-Entry FIFO**

### 10.4.3 General-Purpose Mode

The **General-Purpose Mode Configuration (EPIGPCFG)** register is used to configure the control, data, and address pins, if used. Any unused EPI controller signals can be used as GPIOs or another alternate function. The general-purpose configuration can be used for custom interfaces with FPGAs, CPLDs, and digital data acquisition and actuator control.

**Important:** The RD2CYC bit in the **EPIGPCFG** register must be set at all times in General-Purpose mode to ensure proper operation.

General-Purpose mode is designed for three general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs. Three sizes of data and optional address are supported. Framing and clock-enable functions permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the **EPIBAUD** register baud rate (when used with the WFIFO and/or the NBRFIFO) or by the rate of accesses from software or  $\mu$ DMA. Examples of this type of use include:
  - Reading 20 sensors at fixed time periods by configuring 20 pins to be inputs, configuring the COUNT0 field in the **EPIBAUD** register to some divider, and then using non-blocking reads.

- Implementing a very wide ganged PWM/PCM with fixed frequency for driving actuators, LEDs, etc.
- Implementing SDIO 4-bit mode where commands are driven or captured on 6 pins with fixed timing, fed by the  $\mu$ DMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free-running or gated), a framing signal (with frame size), a ready input (to stretch transactions), a read and write strobe, an address (of varying sizes), and data (of varying sizes). Additionally, provisions are made for separating data and address phases.

The interface has the following optional features:

- Use of the EPI clock output is controlled by the CLKPIN bit in the **EPIGPCFG** register. Unclocked uses include general-purpose I/O and asynchronous interfaces (optionally using RD and WR strobes). Clocked interfaces allow for higher speeds and are much easier to connect to FPGAs and CPLDs (which usually include input clocks).
- EPI clock, if used, may be free running or gated depending on the CLKGATE bit in the **EPIGPCFG** register. A free-running EPI clock requires another method for determining when data is live, such as the frame pin or RD/WR strobes. A gated clock approach uses a setup-time model in which the EPI clock controls when transactions are starting and stopping. The gated clock is held high until a new transaction is started and goes high at the end of the cycle where RD/WR/FRAME and address (and data if write) are emitted.
- Use of the ready input (iRDY) from the external device is controlled by the RDYEN bit in the **EPIGPCFG** register. The iRDY signal uses EPI0S27 and may only be used with a free-running clock. iRDY gates transactions, no matter what state they are in. When iRDY is deasserted, the transaction is held off from completing.
- Use of the frame output (FRAME) is controlled by the FRMPIN bit in the **EPIGPCFG** register. The frame pin may be used whether the clock is output or not, and whether the clock is free running or not. It may also be used along with the iRDY signal. The frame may be a pulse (one clock) or may be 50/50 split across the frame size (controlled by the FRM50 bit in the **EPIGPCFG** register). The frame count (the size of the frame as specified by the FRMCNT field in the **EPIGPCFG** register) may be between 1 and 15 clocks for pulsed and between 2 and 30 clocks for 50/50. The frame pin counts transactions and not clocks; a transaction is any clock where the RD or WR strobe is high (if used). So, if the FRMCNT bit is set, then the frame pin pulses every other transaction; if 2-cycle reads and writes are used, it pulses every other address phase. FRM50 must be used with this in mind as it may hold state for many clocks waiting for the next transaction.
- Use of the RD and WR outputs is controlled by the RW bit in the **EPIGPCFG** register. For interfaces where the direction is known (in advance, related to frame size, or other means), these strobes are not needed. For most other interfaces, RD and WR are used so the external peripheral knows what transaction is taking place, and if any transaction is taking place.
- Separation of address/request and data phases may be used on writes using the WR2CYC bit in the **EPIGPCFG** register. This configuration allows the external peripheral extra time to act. Address and data phases must be separated on reads, and the RD2CYC bit in the **EPIGPCFG** register must be set. When configured to use an address as specified by the ASIZE field in the **EPIGPCFG** register, the address is emitted on the with the RD strobe (first cycle) and data is

expected to be returned on the next cycle (when RD is not asserted). If no address is used, then RD is asserted on the first cycle and data is captured on the second cycle (when RD is not asserted), allowing more setup time for data.

For writes, the output may be in one or two cycles. In the two-cycle case, the address (if any) is emitted on the first cycle with the WR strobe and the data is emitted on the second cycle (with WR not asserted). Although split address and write data phases are not normally needed for logic reasons, it may be useful to make read and write timings match. If 2-cycle reads or writes are used, the RW bit is automatically set.

- Address may be emitted (controlled by the ASIZE field in the **EPIGPCFG** register). The address may be up to 4 bits (16 possible values), up to 12 bits (4096 possible values), or up to 20 bits (1 M possible values). Size of address limits size of data, for example, 4 bits of address support up to 24 bits data. 4-bit address uses EPI0S[27:24]; 12-bit address uses EPI0S[27:16]; 20-bit address uses EPI0S[27:8]. The address signals may be used by the external peripheral as an address, code (command), or for other unrelated uses (such as a chip enable). If the chosen address/data combination does not use all of the EPI signals, the unused pins can be used as GPIOs or for other functions. For example, when using a 4-bit address with an 8-bit data, the pins assigned to EPI0S[23:8] can be assigned to other functions.
- Data may be 8 bits, 16 bits, 24 bits, or 32 bits (controlled by the DSIZE field in the **EPIGPCFG** register). 32-bit data cannot be used with address or EPI clock or any other signal. 24-bit data can only be used with 4-bit address or no address. 32-bit data requires that either the WR2CYC bit or the RD2CYC bit in the **EPIGPCFG** register is set.
- Memory can be used more efficiently by using the Word Access Mode. By default, the EPI controller uses data bits [7:0] when the DSIZE field in the **EPIGPCFG** register is 0x0; data bits [15:0] when the DSIZE field is 0x1; data bits [23:0] when the DSIZE field is 0x2; and data bits [31:0] when the DSIZE field is 0x3. When the WORD bit in the **EPIGPCFG2** register is set, the EPI controller automatically routes bytes of data onto the correct byte lanes such that data can be stored in bits [31:8] for DSIZE=0x0 and bits [31:16] for DSIZE=0x1.
- When using the EPI controller as a GPIO interface, writes are FIFOed (up to 4 can be held at any time), and up to 32 pins are changed using the **EPIBAUD** clock rate specified by COUNT0. As a result, output pin control can be very precisely controlled as a function of time. By contrast, when writing to normal GPIOs, writes can only occur 8-bits at a time and take up to two clock cycles to complete. In addition, the write itself may be further delayed by the bus due to  $\mu$ DMA or draining of a previous write. With both GPIO and the EPI controller, reads may be performed directly, in which case the current pin states are read back. With the EPI controller, the non-blocking interface may also be used to perform reads based on a fixed time rule via the **EPIBAUD** clock rate.

Table 10-7 on page 378 shows how the EPI0S[31:0] signals function while in General-Purpose mode. Notice that the address connections vary depending on the data-width restrictions of the external peripheral.

**Table 10-7. EPI General Purpose Signal Connections**

| EPI Signal | General-Purpose Signal (D8, A20) | General- Purpose Signal (D16, A12) | General- Purpose Signal (D24, A4) | General- Purpose Signal (D32) |
|------------|----------------------------------|------------------------------------|-----------------------------------|-------------------------------|
| EPI0S0     | D0                               | D0                                 | D0                                | D0                            |
| EPI0S1     | D1                               | D1                                 | D1                                | D1                            |
| EPI0S2     | D2                               | D2                                 | D2                                | D2                            |

Table 10-7. EPI General Purpose Signal Connections (*continued*)

| EPI Signal | General-Purpose Signal (D8, A20) | General- Purpose Signal (D16, A12) | General- Purpose Signal (D24, A4) | General- Purpose Signal (D32) |
|------------|----------------------------------|------------------------------------|-----------------------------------|-------------------------------|
| EPI0S3     | D3                               | D3                                 | D3                                | D3                            |
| EPI0S4     | D4                               | D4                                 | D4                                | D4                            |
| EPI0S5     | D5                               | D5                                 | D5                                | D5                            |
| EPI0S6     | D6                               | D6                                 | D6                                | D6                            |
| EPI0S7     | D7                               | D7                                 | D7                                | D7                            |
| EPI0S8     | A0                               | D8                                 | D8                                | D8                            |
| EPI0S9     | A1                               | D9                                 | D9                                | D9                            |
| EPI0S10    | A2                               | D10                                | D10                               | D10                           |
| EPI0S11    | A3                               | D11                                | D11                               | D11                           |
| EPI0S12    | A4                               | D12                                | D12                               | D12                           |
| EPI0S13    | A5                               | D13                                | D13                               | D13                           |

| EPI0S15    | A7                               | D15                                | D15                               | D15                           |
| EPI0S16    | A8                               | A0 <sup>a</sup>                    | D16                               | D16                           |
| EPI0S17    | A9                               | A1                                 | D17                               | D17                           |
| EPI0S18    | A10                              | A2                                 | D18                               | D18                           |
| EPI0S19    | A11                              | A3                                 | D19                               | D19                           |
| EPI0S20    | A12                              | A4                                 | D20                               | D20                           |
| EPI0S21    | A13                              | A5                                 | D21                               | D21                           |
| EPI0S22    | A14                              | A6                                 | D22                               | D22                           |
| EPI0S23    | A15                              | A7                                 | D23                               | D23                           |
| EPI0S24    | A16                              | A8                                 | A0 <sup>b</sup>                   | D24                           |
| EPI0S25    | A17                              | A9                                 | A1                                | D25                           |
| EPI0S26    | A18                              | A10                                | A2                                | D26                           |
| EPI0S27    | A19/iRDY <sup>c</sup>            | A11/iRDY <sup>c</sup>              | A3/iRDY <sup>c</sup>              | D27                           |
| EPI0S28    | WR                               | WR                                 | WR                                | D28                           |
| EPI0S29    | RD                               | RD                                 | RD                                | D29                           |
| EPI0S30    | Frame                            | Frame                              | Frame                             | D30                           |
| EPI0S31    | Clock                            | Clock                              | Clock                             | D31                           |

a. In this mode, half-word accesses are used. A0 is the LSB of the address and is equivalent to the system A1 address.

b. In this mode, word accesses are used. A0 is the LSB of the address and is equivalent to the system A2 address.

c. This signal is iRDY if the RDYEN bit in the **EPIGPCFG** register is set.

### 10.4.3.1 Bus Operation

A basic access is 1 EPI clock for write cycles and 2 EPI clocks for read cycles. An additional EPI clock can be inserted into a write cycle by setting the WR2CYC bit in the **EPIGPCFG** register. Note that the RD2CYC bit must always be set in the **EPIGPCFG** register. If the iRDY signal is deasserted, further transactions are held off until the iRDY signal is asserted again.

**Figure 10-11. Single-Cycle Write Access, FRM50=0, FRMCNT=0, WRCYC=0**

**Figure 10-12. Two-Cycle Read, Write Accesses, FRM50=0, FRMCNT=0, RDCYC=1, WRCYC=1**

**Figure 10-13. Read Accesses, FRM50=0, FRMCNT=0, RDCYC=1****FRAME Signal Operation**

The operation of the FRAME signal is controlled by the FRMCNT and FRM50 bits. When FRM50 is clear, the FRAME signal is high whenever the WR or RD strobe is high. When FRMCNT is clear, the FRAME signal is simply the logical OR of the WR and RD strobes so the FRAME signal is high during every read or write access, see Figure 10-14 on page 381.

**Figure 10-14. FRAME Signal Operation, FRM50=0 and FRMCNT=0**

If the FRMCNT field is 0x1, then the FRAME signal pulses high during every other read or write access, see Figure 10-15 on page 381.

**Figure 10-15. FRAME Signal Operation, FRM50=0 and FRMCNT=1**

If the FRMCNT field is 0x2 and FRM50 is clear, then the FRAME signal pulses high during every third access, and so on for every value of FRMCNT, see Figure 10-16 on page 382.

**Figure 10-16. FRAME Signal Operation, FRM50=0 and FRMCNT=2**

When FRM50 is set, the FRAME signal transitions on the rising edge of either the WR or RD strobes. When FRMCNT=0, the FRAME signal transitions on the rising edge of WR or RD for every access, see Figure 10-17 on page 382.

**Figure 10-17. FRAME Signal Operation, FRM50=1 and FRMCNT=0**

When FRMCNT=1, the FRAME signal transitions on the rising edge of the WR or RD strobes for every other access, see Figure 10-18 on page 382.

**Figure 10-18. FRAME Signal Operation, FRM50=1 and FRMCNT=1**

When FRMCNT=2, the FRAME signal transitions the rising edge of the WR or RD strobes for every third access, and so on for every value of FRMCNT, see Figure 10-19 on page 382.

**Figure 10-19. FRAME Signal Operation, FRM50=1 and FRMCNT=2**

### iRDY Signal Operation

The ready input (iRDY) from the external device is enabled by the RDYEN bit in the **EPIGPCFG** register. iRDY is input on EPI0S27 and may only be used with a free-running clock (CLKGATE is clear). iRDY is sampled on the falling edge of the EPI clock and gates transactions, no matter what state they are in. Figure 10-20 on page 383 shows the iRDY signal being recognized as deasserted on the falling edge of T1. The FRAME, RD, Address, Data signals behave as they would during a normal transaction in T1. T2 is the frozen state, and signals are held in this state until iRDY is recognized as asserted again. At the falling edge of T2, when iRDY is asserted again, the cycle continues and completes in T3.

**Figure 10-20. iRDY Signal Operation, FRM50=0, FRMCNT=0, and RD2CYC=1**

### EPI Clock Operation

If the CLKGATE bit in the **EPIGPCFG** register is clear, the EPI clock always toggles when General-purpose mode is enabled. If CLKGATE is set, the clock is output only when a transaction is occurring, otherwise the clock is held high. If the WR2CYC bit is clear, the EPI clock begins toggling 1 cycle before the WR strobe goes high. If the WR2CYC bit is set, the EPI clock begins toggling when the WR strobe goes high. The clock stops toggling after the first rising edge after the WR strobe is deasserted. The RD strobe operates in the same manner as the WR strobe when the WR2CYC bit is set, as the RD2CYC bit must always be set. See Figure 10-21 on page 383 and Figure 10-22 on page 384.

**Figure 10-21. EPI Clock Operation, CLKGATE=1, WR2CYC=0**

**Figure 10-22. EPI Clock Operation, CLKGATE=1, WR2CYC=1**

## 10.5 Register Map

Table 10-8 on page 384 lists the EPI registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address of 0x400D.0000. Note that the EPI controller clock must be enabled before the registers can be programmed (see page 179).

**Note:** A back-to-back write followed by a read of the same register reads the value that written by the first write access, not the value from the second write access. (This situation only occurs when the processor core attempts this action, the  $\mu$ DMA does not do this.). To read back what was just written, another instruction must be generated between the write and read. Read-write does not have this issue, so use of read-write for clear of error interrupt cause is not affected.

**Table 10-8. External Peripheral Interface (EPI) Register Map**

## 10.6 Register Descriptions

This section lists and describes the EPI registers, in numerical order by address offset.

**Register 1: EPI Configuration (EPICFG), offset 0x000**

**Important:** The MODE field determines which configuration register is accessed for offsets 0x010 and 0x014. Any write to the **EPICFG** register resets the register contents at offsets 0x010 and 0x014.

The configuration register is used to enable the block, select a mode, and select the basic pin use (based on the mode). Note that attempting to program an undefined MODE field clears the BLKEN bit and disables the EPI controller.

**EPI Configuration (EPICFG)**

|           |      |      |         | Value    Description                                                                                                                                                   |
|           |      |      | 0x0     | General Purpose                                                                                                                                                        |
|           |      |      |         | General-Purpose mode. Control, address, and data pins are configured using the <b>EPIGPCFG</b> and <b>EPIGPCFG2</b> registers.                                         |
|           |      |      | 0x1     | SDRAM                                                                                                                                                                  |
|           |      |      |         | Supports SDR SDRAM. Control, address, and data pins are configured using the <b>EPISDRAMCFG</b> register.                                                              |
|           |      |      | 0x2     | 8-Bit Host-Bus (HB8)                                                                                                                                                   |
|           |      |      |         | Host-bus 8-bit interface (also known as the MCU interface). Control, address, and data pins are configured using the <b>EPIHB8CFG</b> and <b>EPIHB8CFG2</b> registers. |
|           |      |      | 0x3     | 16-Bit Host-Bus (HB16)                                                                                                                                                 |
|           |      |      |         | Host-bus 16-bit interface (standard SRAM). Control, address, and data pins are configured using the <b>EPIHB16CFG</b> and <b>EPIHB16CFG2</b> registers.                |
|           |      |      | 0x3-0xF | Reserved                                                                                                                                                               |

**Register 2: EPI Main Baud Rate (EPIBAUD), offset 0x004**

The system clock is used internally to the EPI Controller. The baud rate counter can be used to divide the system clock down to control the speed on the external interface. If the mode selected emits an external EPI clock, this register defines the EPI clock emitted. If the mode selected does not use an EPI clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins. COUNT0 is the bit field used in all modes except in HB8 and HB16 modes with dual chip selects when different baud rates are selected, see page 405. If different baud rates are used, COUNT0 is associated with the address range specified by CS0 and COUNT1 is associated with the address range specified by CS1.

The COUNTn field is not a straight divider or count. The EPI Clock on EPI0S31 is related to the COUNTn field and the system clock as follows:

If COUNTn = 0,

$$EPIClockFreq = SystemClockFreq$$

otherwise:

$$EPIClockFreq = \frac{SystemClockFreq}{\left( \left\lfloor \frac{COUNTn}{2} \right\rfloor + 1 \right) \times 2}$$

where the symbol around COUNTn/2 is the floor operator, meaning the largest integer less than or equal to COUNTn/2.

So, for example, a COUNTn of 0x0001 results in a clock rate of 1/2(system clock); a COUNTn of 0x0002 or 0x0003 results in a clock rate of 1/4(system clock).

### Register 3: EPI SDRAM Configuration (EPISDRAMCFG), offset 0x010

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPISDRAMCFG**, the MODE field must be 0x1.

The SDRAM Configuration register is used to specify several parameters for the SDRAM controller. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the SDRAM mode is selected again, the values must be reinitialized.

The SDRAM interface designed to interface to x16 SDR SDRAMs of 64 MHz or higher, with the address and data pins overlapped (wire ORed on the board). See Table 10-3 on page 364 for pin assignments.

#### EPI SDRAM Configuration (EPISDRAMCFG)

Base 0x400D.0000

Offset 0x010

Type R/W, reset 0x42EE.0000

**Register 4: EPI Host-Bus 8 Configuration (EPIHB8CFG), offset 0x010**

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB8CFG**, the MODE field must be 0x2.

The Host Bus 8 Configuration register is activated when the HB8 mode is selected. The HB8 mode supports muxed address/data (overlay of lower 8 address and all 8 data pins), separated address/data, and address-less FIFO mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the HB8 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, CPLDs/FPGAs, and devices with an MCU/HostBus slave or 8-bit FIFO interface support.

Refer to Table 10-5 on page 369 for information on signal configuration controlled by this register and the **EPIHB8CFG2** register.

If less address pins are required, the corresponding AFSEL bit (page 324) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

There is no direct chip enable (CE) model. Instead, CE can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins EPI0S27 and EPI0S26 are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent WRn or RDn signals write or read when ALE is low thus providing CEn functionality.

**Register 5: EPI Host-Bus 16 Configuration (EPIHB16CFG), offset 0x010**

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB16CFG**, the MODE field must be 0x3.

The Host Bus 16 sub-configuration register is activated when the HB16 mode is selected. The HB16 mode supports muxed address/data (overlay of lower 16 address and all 16 data pins), separated address/data, and address-less FIFO mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the HB16 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, and CPLDs/FPGAs, and devices with an MCU/HostBus slave or 16-bit FIFO interface support.

Refer to Table 10-6 on page 370 for information on signal configuration controlled by this register and the **EPIHB16CFG2** register.

If less address pins are required, the corresponding AFSEL bit (page 324) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

There is no direct chip enable (CE) model. Instead, CE can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins EPI0S27 and EPI0S26 are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent WRn or RDn signals write or read when ALE is low thus providing CEn functionality.

This mode uses no address or ALE.</p> |

**Register 6: EPI General-Purpose Configuration (EPIGPCFG), offset 0x010**

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIGPCFG**, the MODE field must be 0x0.

The RD2CYC bit must be set at all times in General-Purpose mode to ensure proper operation.

The General-Purpose configuration register is used to configure the control, data, and address pins. This mode can be used for custom interfaces with FPGAs, CPLDs, and for digital data acquisition and actuator control. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the General-purpose mode is selected again, the register the values must be reinitialized.

This mode is designed for 3 general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs, with 3 sizes of data and optional address. Framing and clock-enable permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the baud rate in the **EPIBAUD** register (when used with the NBRFIFO and/or the WFIFO) or by rate of accesses from software or  $\mu$ DMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free running or gated), a framing signal (with frame size), a ready input (to stretch transactions), read and write strobes, address of varying sizes, and data of varying sizes. Additionally, provisions are made for splitting address and data phases on the external interface.

**EPI General-Purpose Configuration (EPIGPCFG)**

Value Description

1 EPI0S31 functions as the EPI clock output.

0 No clock output.

The EPI clock is generated from the COUNT0 field in the **EPIBAUD** register (as is the system clock which is divided down from it).

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 1                                                                                                                   | RD and WR strobes are asserted on EPI0S29 and EPI0S28. RD is asserted high on the rising edge of the EPI clock when a read is being performed. WR is asserted high on the rising edge of the EPI clock when a write is being performed       |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |             |   |                                                                                                                                                                                                                                              |   |                                                                    |

The address can be up to 4-bits wide with a 24-bit data bus, up to 12-bits wide with a 16-bit data bus, and up to 20-bits wide with an 8-bit data bus. If the full address bus is not used, use the least significant address bits. Any unused address bits can be used as GPIOs by clearing the AFSEL bit for the corresponding GPIOs. Also, if RDYEN is 1, then the address sizes are 1 smaller (3, 11, 19).</p> <p>The values are:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>No address</td></tr><tr><td>0x1</td><td>Up to 4 bits wide.</td></tr><tr><td>0x2</td><td>Up to 12 bits wide. ## Register 7: EPI Host-Bus 8 Configuration 2 (EPIHB8CFG2), offset 0x014

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB8CFG2**, the MODE field must be 0x2.

This register is used to configure operation while in Host-Bus 8 mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the Host-Bus 8 mode is selected again, the values must be reinitialized.

### EPI Host-Bus 8 Configuration 2 (EPIHB8CFG2)

Base 0x400D.0000

Offset 0x014

Type R/W, reset 0x0000.0000

| 25:24     | CSCFG    | R/W  | 0x0   | <p>Chip Select Configuration</p> <p>Value Description</p> <p>0x0 ALE Configuration</p> <p>EPI0S30 is used as an address latch (ALE). When using this mode, the address and data should be muxed (HB8MODE field in the <b>EPIHB8CFG</b> register should be configured to 0x0). If needed, the address can be latched by external logic.</p> <p>0x1 CSn Configuration</p> <p>EPI0S30 is used as a Chip Select (CSn). When using this mode, the address and data should not be muxed (HB8MODE field in the <b>EPIHB8CFG</b> register should be configured to 0x1). In this mode, the WR signal (EPI0S29) and the RD signal (EPI0S28) are used to latch the address when CSn is low.</p> <p>0x2 Dual CSn Configuration</p> <p>EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.</p> <p>0x3 ALE with Dual CSn Configuration</p> <p>EPI0S30 is used as address latch (ALE), EPI0S27 is used as CS1n, and EPI0S26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.</p> |
| 23:0      | reserved | RO   | 0x0   | <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Register 8: EPI Host-Bus 16 Configuration 2 (EPIHB16CFG2), offset 0x014

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB16CFG2**, the MODE field must be 0x3.

This register is used to configure operation while in Host-Bus 16 mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the Host-Bus 16 mode is selected again, the values must be reinitialized.

### EPI Host-Bus 16 Configuration 2 (EPIHB16CFG2)

Base 0x400D.0000

Offset 0x014

Type R/W, reset 0x0000.0000

| 25:24     | CSCFG    | R/W  | 0x0   | <p>Chip Select Configuration</p> <p>This field controls the chip select options, including an ALE format, a single chip select, two chip selects, and an ALE combined with two chip selects.</p> <p>Value Description</p> <p>0x0 ALE Configuration</p> <p>EPI0S30 is used as an address latch (ALE). When using this mode, the address and data should be muxed (HB16MODE field in the <b>EPIHB16CFG</b> register should be configured to 0x0). If needed, the address can be latched by external logic.</p> <p>0x1 CSn Configuration</p> <p>EPI0S30 is used as a Chip Select (CSn). When using this mode, the address and data should not be muxed (HB816MODE field in the <b>EPIHB16CFG</b> register should be configured to 0x1). In this mode, the WR signal (EPI0S29) and the RD signal (EPI0S28) are used to latch the address when CSn is low.</p> <p>0x2 Dual CSn Configuration</p> <p>EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.</p> <p>0x3 ALE with Dual CSn Configuration</p> <p>EPI0S30 is used as address latch (ALE), EPI0S27 is used as CS1n, and EPI0S26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.</p> |

## Register 9: EPI General-Purpose Configuration 2 (EPIGPCFG2), offset 0x014

**Important:** The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIGPCFG2**, the MODE field must be 0x0.

This register is used to configure operation while in General-Purpose mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the General-Purpose mode is selected again, the values must be reinitialized.

## Register 10: EPI Address Map (EPIADDRMAP), offset 0x01C

This register enables address mapping. The EPI controller can directly address memory and peripherals. In addition, the EPI controller supports address mapping to allow indirect accesses in the External RAM and External Peripheral areas.

If the external device is a peripheral, including a FIFO or a directly addressable device, the EPSZ and EPADR bit fields should be configured for the address space. If the external device is SDRAM, SRAM, or NOR Flash memory, the ERADR and ERSZ bit fields should be configured for the address space.

If one of the Dual-Chip-Select modes is selected (CSCFG=0x2 or 0x3 in the **EPIHBnCFG2** register), both chip selects can share the peripheral or the memory space, or one chip select can use the peripheral space and the other can use the memory space. If the EPADR field is not 0x0 and the ERADR field is 0x0, then the address specified by EPADR is used for both chip selects, with CS0n being asserted when the MSB of the address range is 0 and CS1n being asserted when the MSB of the address range is 1. If the ERADR field is not 0x0 and the EPADR field is 0x0, then the address specified by ERADR is used for both chip selects, with the MSB performing the same delineation. If both the EPADR and the ERADR are not 0x0, then CS0n is asserted for the address range defined by EPADR and CS1n is asserted for the address range defined by ERADR.

| 7:6                                                                                                                                                                                                                    | EPSZ | R/W | 0x0 | External Peripheral Size |
| This field selects the size of the external peripheral. If the size of the external peripheral is larger, a bus fault occurs. If the size of the external peripheral is smaller, it wraps (upper address bits unused). |      |     |     |                          |

**Note:** When not using byte selects in Host-Bus 16, data is accessed on 2-byte boundaries. As a result, the available address space is double the amount shown below.

| Value | Description                                           |

Register 11: EPI Read Size 0 (EPIRSIZE0), offset 0x020

Register 12: EPI Read Size 1 (EPIRSIZE1), offset 0x030

This register selects the size of transactions when performing non-blocking reads with the **EPIRPSTDn** registers. This size affects how the external address is incremented.

The **SIZE** field must match the external data width as configured in the **EPIHBnCFG** or **EPIGPCFG** register.

SDRAM mode uses a 16-bit data interface. If **SIZE** is 0x1, data is returned on the least significant bits (D[7:0]), and the remaining bits D[31:8] are all zeros, therefore the data on bits D[15:8] is lost. If **SIZE** is 0x2, data is returned on the least significant bits (D[15:0]), and the remaining bits D[31:16] are all zeros.

Note that changing this register while a read is active has an unpredictable effect.

**Register 13: EPI Read Address 0 (EPIRADDR0), offset 0x024****Register 14: EPI Read Address 1 (EPIRADDR1), offset 0x034**

This register holds the current address value. When performing non-blocking reads via the **EPIRPSTDn** registers, this register's value forms the address (when used by the mode). That is, when an **EPIRPSTDn** register is written with a non-0 value, this register is used as the first address. After each read, it is incremented by the size specified by the corresponding **EPIRSIZEn** register. Thus at the end of a read, this register contains the next address for the next read. For example, if the last read was 0x20, and the size is word, then the register contains 0x24. When a non-blocking read is cancelled, this register contains the next address that would have been read had it not been cancelled. For example, if reading by bytes and 0x103 had been read but not 0x104, this register contains 0x104. In this manner, the system can determine the number of values in the NBRFIFO to drain.

Note that changing this register while a read is active has an unpredictable effect due to race condition.

**Register 15: EPI Non-Blocking Read Data 0 (EPIRPSTD0), offset 0x028****Register 16: EPI Non-Blocking Read Data 1 (EPIRPSTD1), offset 0x038**

This register sets up a non-blocking read via the external interface. A non-blocking read is started by writing to this register with the count (other than 0). Clearing this register terminates an active non-blocking read as well as cancelling any that are pending. This register should always be cleared before writing a value other than 0; failure to do so can cause improper operation.

The first address is based on the corresponding **EPIADDRn** register. The address register is incremented by the size specified by the **EPIRSIZEn** register after each read. If the size is less than a word, only the least significant bits of data are filled into the NBRFIFO; the most significant bits are cleared.

Note that all three registers may be written using one STM instruction, such as with a structure copy in C/C++.

The data may be read from the **EPIREADFIFO** register after the read cycle is completed. The interrupt mechanism is normally used to trigger the FIFO reads via ISR or  $\mu$ DMA.

If the countdown has not reached 0 and the NBRFIFO is full, the external interface waits until a NBRFIFO entry becomes available to continue.

Note: if a blocking read or write is performed through the address mapped area (at 0x6000.0000 through 0xDFFF.FFFF), any current non-blocking read is paused (at the next safe boundary), and the blocking request is inserted. After completion of any blocking reads or writes, the non-blocking reads continue from where they were paused.

The other way to read data is via the address mapped locations (see the **EPIADDRMAP** register), but this method is blocking (core or  $\mu$ DMA waits until result is returned).

To cancel a non-blocking read, clear this register. To make sure that all values read are drained from the NBRFIFO, the **EPISTAT** register must be consulted to be certain that bits NBRBUSY and ACTIVE are cleared. One of these registers should not be cleared until either the other **EPIRPSTDn** register becomes active or the external interface is not busy. At that point, the corresponding **EPIADDRn** register indicates how many values were read.

**EPI Non-Blocking Read Data 0 (EPIRPSTD0)**

**Register 17: EPI Status (EPISTAT), offset 0x060**

This register indicates which non-blocking read register is currently active; it also indicates whether the external interface is busy performing a write or non-blocking read (it cannot be performing a blocking read, as the bus would be blocked and as a result, this register could not be accessed).

This register is useful to determining which non-blocking read register is active when both are loaded with values and when implementing sequencing or sharing.

This register is also useful when canceling non-blocking reads, as it shows how many values were read by the canceled side.

**Register 18: EPI Read FIFO Count (EPIRFIFOCNT), offset 0x06C**

This register returns the number of values in the NBRFIFO (the data in the NBRFIFO can be read via the **EPIREADFIFO** register). A race is possible, but that only means that more values may come in after this register has been read.

**EPI Read FIFO Count (EPIRFIFOCNT)**

**Register 19: EPI Read FIFO (EPIREADFIFO), offset 0x070**

**Register 20: EPI Read FIFO Alias 1 (EPIREADFIFO1), offset 0x074**

**Register 21: EPI Read FIFO Alias 2 (EPIREADFIFO2), offset 0x078**

**Register 22: EPI Read FIFO Alias 3 (EPIREADFIFO3), offset 0x07C**

**Register 23: EPI Read FIFO Alias 4 (EPIREADFIFO4), offset 0x080**

**Register 24: EPI Read FIFO Alias 5 (EPIREADFIFO5), offset 0x084**

**Register 25: EPI Read FIFO Alias 6 (EPIREADFIFO6), offset 0x088**

**Register 26: EPI Read FIFO Alias 7 (EPIREADFIFO7), offset 0x08C**

**Important:** Use caution when reading this register. Performing a read may change bit status.

This register returns the contents of the NBRFIFO or 0 if the NBRFIFO is empty. Each read returns the data that is at the top of the NBRFIFO, and then empties that value from the NBRFIFO. The alias registers can be used with the LDMIA instruction for more efficient operation (for up to 8 registers). See *ARM® Cortex™-M3 Technical Reference Manual* for more information on the LDMIA instruction.

| 31:0      | DATA | RO   | -     | Reads Data  |

This field contains the data that is at the top of the NBRFIFO. After being read, the NBRFIFO entry is removed.

**Register 27: EPI FIFO Level Selects (EPIFIFOLVL), offset 0x200**

This register allows selection of the FIFO levels which trigger an interrupt to the interrupt controller or, more efficiently, a DMA request to the  $\mu$ DMA. The NBRFIFO select triggers on fullness such that it triggers on match or above (more full). The WFIFO triggers on emptiness such that it triggers on match or below (less entries).

It should be noted that the FIFO triggers are not identical to other such FIFOs in Stellaris<sup>®</sup> peripherals. In particular, empty and full triggers are provided to avoid wait states when using blocking operations.

The settings in this register are only meaningful if the  $\mu$ DMA is active or the interrupt is enabled.

Additionally, this register allows protection against writes stalling and notification of performing blocking reads which stall for extra time due to preceding writes. The two functions behave in a non-orthogonal way because read and write are not orthogonal.

The write error bit configures the system such that an attempted write to an already full WFIFO abandons the write and signals an error interrupt to prevent accidental latencies due to stalling writes.

The read error bit configures the system such that after a read has been stalled due to any preceding writes in the WFIFO, the error interrupt is generated. Note that the excess stall is not prevented, but an interrupt is generated after the fact to notify that it has happened.

**EPI FIFO Level Selects (EPIFIFOLVL)**

|           |          |      |       | Value Description                                                                                                                                                                                                                                                               |
|           |          |      |       | 1 This bit enables the Write Full error interrupt (WTFULL in the <b>EPIIC</b> register) to be generated when a write is attempted and the WFIFO is full. The write stalls until a WFIFO entry becomes available.                                                                |
|           |          |      |       | 0 The Write Full error interrupt is disabled. Writes are stalled when the WFIFO is full until a space becomes available but an error is not generated. Note that the Cortex-M3 write buffer may hide that stall if no other memory transactions are attempted during that time. |

Register 28: EPI Write FIFO Count (EPIWFIFOCNT), offset 0x204

This register contains the number of slots currently available in the WFIFO. This register may be used for polled writes to avoid stalling and for blocking reads to avoid excess stalling (due to undrained writes). An example use for writes may be:

```
for (idx = 0; idx < cnt; idx++) {
while (EPIWFIFOCNT == 0) ;
*ext_ram = *mydata++;
}
```

The above code ensures that writes to the address mapped location do not occur unless the WFIFO has room. Although polling makes the code wait (spinning in the loop), it does not prevent interrupts being serviced due to bus stalling.

**Register 29: EPI Interrupt Mask (EPIIM), offset 0x210**

This register is the interrupt mask set or clear register. For each interrupt source (read, write, and error), a mask value of 1 allows the interrupt source to trigger an interrupt to the interrupt controller; a mask value of 0 prevents the interrupt source from triggering an interrupt.

Note that interrupt masking has no effect on  $\mu$ DMA, which operates off the raw source of the read and write interrupts.

**Register 30: EPI Raw Interrupt Status (EPIRIS), offset 0x214**

This register is the raw interrupt status register. On a read, it gives the current state of each interrupt source. A write has no effect.

Note that raw status for read and write is set or cleared based on FIFO fullness as controlled by **EPIFIFOLVL**.

Raw status for error is held until the error is cleared by writing to the **EPIIC** register.

**EPI Raw Interrupt Status (EPIRIS)**

**Register 31: EPI Masked Interrupt Status (EPIMIS), offset 0x218**

This register is the masked interrupt status register. On read, it gives the current state of each interrupt source (read, write, and error) after being masked via the **EPIIM** register. A write has no effect.

The values returned are the ANDing of the **EPIIM** and **EPIRIS** registers. If a bit is set in this register, the interrupt is sent to the interrupt controller.

## Register 32: EPI Error Interrupt Status and Clear (EPIEISC), offset 0x21C

This register is used to clear a pending error interrupt. If any of these bits are set, the ERRRIS bit in the **EPIRIS** register is set, and an EPI controller error is sent to the interrupt controller if the ERIM bit in the **EPIIM** register is set. Clearing any defined bit has no effect; setting a bit clears the error source and the raw error returns to 0. Note that writing to this register and reading back immediately (pipelined by the processor) returns the old register contents. One cycle is needed between write and read.

## 11 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris® General-Purpose Timer Module (GPTM) contains four GPTM blocks (Timer 0, Timer 1, Timer 2, and Timer 3). Each GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger  $\mu$ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Stellaris® microcontrollers. Other timer resources include the System Timer (SysTick) (see “System Timer (SysTick)” on page 78) and the PWM timer in the PWM module (see “PWM Timer” on page 968).

The General-Purpose Timer Module (GPTM) contains four GPTM blocks with the following functional options:

- Count up or down
- 16- or 32-bit programmable one-shot timer
- 16- or 32-bit programmable periodic timer
- 16-bit general-purpose timer with an 8-bit prescaler
- 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
- Eight Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- ADC event trigger
- User-enabled stalling when the controller asserts CPU Halt flag during debug (excluding RTC mode)
- 16-bit input-edge count- or time-capture modes
- 16-bit PWM mode with software-programmable output inversion of the PWM signal
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

## 11.1 Block Diagram

Figure 11-1. GPTM Module Block Diagram

**Note:** In Figure 11-1 on page 430, the specific Capture Compare PWM (CCP) pins available depend on the Stellaris<sup>®</sup> device. See Table 11-1 on page 430 for the available CCP pins and their timer assignments

Table 11-1. Available CCP Pins

| Timer   | 16-Bit Up/Down Counter | Even CCP Pin | Odd CCP Pin |
|---------|------------------------|--------------|-------------|
| Timer 0 | Timer A                | CCP0         | -           |
|         | Timer B                | -            | CCP1        |
| Timer 1 | Timer A                | CCP2         | -           |
|         | Timer B                | -            | CCP3        |
| Timer 2 | Timer A                | CCP4         | -           |
|         | Timer B                | -            | CCP5        |
| Timer 3 | Timer A                | CCP6         | -           |
|         | Timer B                | -            | CCP7        |

## 11.2 Signal Description

Table 11-2 on page 431 and Table 11-3 on page 432 list the external signals of the GP Timer module and describe the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 324) should be set to choose

the GP Timer function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 342) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 299.

**Table 11-2. Signals for General-Purpose Timers (100LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description            |
|----------|------------|--------------------------|----------|--------------------------|------------------------|
| CCP0     | 13         | PD3 (4)                  | I/O      | TTL                      | Capture/Compare/PWM 0. |
|          | 22         | PC7 (4)                  |          |                          |                        |
|          | 23         | PC6 (6)                  |          |                          |                        |

|          | A12        | PE1 (5)                  |          |                          |                        |
|          | C9         | PH0 (1)                  |          |                          |                        |
| CCP7     | B7         | PB5 (3)                  | I/O      | TTL                      | Capture/Compare/PWM 7. |
|          | G2         | PD1 (6)                  |          |                          |                        |
|          | H1         | PD3 (2)                  |          |                          |                        |
|          | C8         | PH1 (1)                  |          |                          |                        |
|          | A7         | PB6 (2)                  |          |                          |                        |
|          | B4         | PE3 (5)                  |          |                          |                        |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 11.3 Functional Description

The main components of each GPTM block are two free-running 16-bit up/down counters (referred to as Timer A and Timer B), two 16-bit match registers, two prescaler match registers, two 16-bit shadow registers, and two 16-bit load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface.

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 446), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 447), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 449). When in one of the 32-bit modes, the timer can only act as a 32-bit timer. However, when configured in 16-bit mode, the GPTM can have its two 16-bit timers configured in any combination of the 16-bit modes.

### 11.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to

0xFFFF, along with their corresponding load registers: the **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 464) and the **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 465) and shadow registers: the **GPTM Timer A Value (GPTMTAV)** register (see page 475) and the **GPTM Timer B Value (GPTMTBV)** register (see page 476). The prescale counters are initialized to 0x00: the **GPTM Timer A Prescale (GPTMTAPR)** register (see page 468) and the **GPTM Timer B Prescale (GPTMTBPR)** register (see page 469).

### 11.3.2 32-Bit Timer Operating Modes

This section describes the three GPTM 32-bit timer modes (One-Shot, Periodic, and RTC) and their configurations.

The GPTM is placed into 32-bit mode by writing a 0x0 (One-Shot/Periodic 32-bit timer mode) or a 0x1 (RTC mode) to the GPTMCFG bit field in the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR)** register [15:0], see page 464
- **GPTM Timer B Interval Load (GPTMTBILR)** register [15:0], see page 465
- **GPTM Timer A (GPTMTAR)** register [15:0], see page 472
- **GPTM Timer B (GPTMTBR)** register [15:0], see page 473
- **GPTM Timer A Value (GPTMTAV)** register [15:0], see page 475
- **GPTM Timer B Value (GPTMTBV)** register [15:0], see page 476

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

GPTMTBILR[15:0] : GPTMTAILR[15:0]

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

GPTMTBR[15:0] : GPTMTAR[15:0]

A 32-bit read access to **GPTMTAV** returns the value:

GPTMTBV[15:0] : GPTMTAV[15:0]

#### 11.3.2.1 32-Bit One-Shot/Periodic Timer Mode

In 32-bit one-shot and periodic timer modes, the concatenated versions of the Timer A and Timer B registers are configured as a 32-bit up or down counter. The selection of one-shot or periodic mode is determined by the value written to the TAMR field of the **GPTM Timer A Mode (GPTMTAMR)** register (see page 447); there is no need to write to the **GPTM Timer B Mode (GPTMTBMR)** register. The timer is configured to count up or down using the TACDIR bit in the **GPTMTAMR** register.

When software sets the TAEN bit in the **GPTM Control (GPTMCTL)** register (see page 451), the timer begins counting up from 0x0000.0000 or down from its preloaded value. Alternatively, if the TAWOT bit is set in the **GPTMTAMR** register, once the TAEN bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 440).

When the timer is counting down and it reaches the time-out event (0x0000.0000), the timer reloads its start value from the concatenated **GPTMTAILR** on the next cycle. When the timer is counting

up and it reaches the time-out event (the value in the concatenated **GPTMTAILR**), the timer starts counting again from 0x0000.0000 on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the TAEN bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting. In periodic, snap-shot mode (TASNAPS bit in the **GPTMTAMR** register is set), the actual free-running value of the timer at the time-out event is loaded into the **GPTMTAR** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the time-out event. The GPTM sets the TATORIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 456), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 462). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTIMR)** register (see page 454), the GPTM also sets the TATOMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 459). By setting the TAMIE bit in the **GPTMTAMR** register, an interrupt can also be generated when the Timer A value equals the value loaded into the **GPTM Timer A Match (GPTMTAMATCH)** register. This interrupt has the same status, masking, and clearing functions as the time-out interrupt. The ADC trigger is enabled by setting the TAOTE bit in **GPTMCTL**. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 245.

If software updates the **GPTMTAILR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting down from the new value. If software updates the **GPTM Timer A Value (GPTMTAV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the TASTALL bit in the **GPTMCTL** register is set, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution.

### 11.3.2.2 32-Bit Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as a 32-bit up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x0000.0001. All subsequent load values must be written to the **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 464).

The input clock on an even CCP input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the 32-bit counter.

When software writes the TAEN bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x0000.0001. When the current count value matches the preloaded value in the **GPTMTAMATCHR** register, the GPTM asserts the RTCRIS bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the TAEN bit). When the timer value reaches 0xFFFF.FFFF, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTIMR**, the GPTM also sets the RTCMIS bit in **GPTMISR** and generates a controller interrupt. The status flags are cleared by writing the RTCCINT bit in **GPTMICR**.

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 245.

If the TASTALL and/or TBSTALL bits in the **GPTMCTL** register are set, the timer does not freeze if the RTCEN bit is set in **GPTMCTL**.

### 11.3.3 16-Bit Timer Operating Modes

The GPTM is placed into global 16-bit mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 446). This section describes each of the GPTM 16-bit modes of

operation. Timer A and Timer B have identical modes, so a single description is given using an **n** to reference both.

### 11.3.3.1 16-Bit One-Shot/Periodic Timer Mode

In 16-bit one-shot and periodic timer modes, the timer is configured as a 16-bit up or down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. The selection of one-shot or periodic mode is determined by the value written to the **TnMR** field of the **GPTMTnMR** register. The optional prescaler is loaded into the **GPTM Timer n Prescale (GPTMTnPR)** register. The timer is configured to count up or down using the **TnCDIR** bit in the **GPTMTnMR** register.

When software sets the **TnEN** bit in the **GPTMCTL** register, the timer begins counting up from 0x0000.0000 or down from its preloaded value. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 440).

When the timer is counting down and it reaches the time-out event (0x0000), the timer reloads its start value from the concatenated **GPTMTnILR** and **GPTMTnPR** on the next cycle. When the timer is counting up and it reaches the time-out event (the value in the **GPTMTnILR**), the timer starts counting again from 0x0000 on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the **TnEN** bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting. In periodic, snap-shot mode, (**TnSNAPS** bit in the **GPTMTnMR** register is set), the actual free-running value of the timer at the time-out event is loaded into the **GPTMTAR** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry.

In addition to reloading the count value, the timer generates interrupts and triggers when it reaches the time-out event. The GPTM sets the **TnTORIS** bit in the **GPTMRIS** register, and holds it until it is cleared by writing the **GPTMICR** register. If the time-out interrupt is enabled in **GPTIMR**, the GPTM also sets the **TnTOMIS** bit in **GPTMISR** and generates a controller interrupt. By setting the **TnMIE** bit in the **GPTMTnMR** register, an interrupt can also be generated when the timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCH)** register. This interrupt has the same status, masking, and clearing functions as the time-out interrupt. The ADC trigger is enabled by setting the **Tn0TE** bit in the **GPTMCTL** register. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 245.

If software updates the **GPTMTnILR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting down from the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the **TnSTALL** bit in the **GPTMCTL** register is set, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution.

The following example shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume an 80-MHz clock with  $T_c=12.5$  ns (clock period).

**Table 11-4. 16-Bit Timer With Prescaler Configurations**

| Prescale | #Clock ( $T_c$ ) <sup>a</sup> | Max Time | Units |
|----------|-------------------------------|----------|-------|
| 00000000 | 1                             | 0.8192   | mS    |
| 00000001 | 2                             | 1.6384   | mS    |
| 00000010 | 3                             | 2.4576   | mS    |
| .....    | ...                           | ...      | ...   |

**Table 11-4. 16-Bit Timer With Prescaler Configurations (continued)**

| Prescale | #Clock (Tc) <sup>a</sup> | Max Time | Units |
|----------|--------------------------|----------|-------|
| 11111101 | 254                      | 208.0768 | mS    |
| 11111110 | 255                      | 208.896  | mS    |
| 11111111 | 256                      | 209.7152 | mS    |

a. Tc is the clock period.

### 11.3.3.2 Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Count mode, the timer is configured as a 24-bit down-counter with the MSB stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the remaining 16 bits in the **GPTMTnILR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the TnCMR bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the TnEVENT fields of the **GPTMCTL** register. During initialization, the **GPTM Timer n Match (GPTMTnMATCHR)** register is configured so that the difference between the value in the **GPTMTnILR** register and the **GPTMTnMATCHR** register equals the number of edge events that must be counted.

When software writes the TnEN bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements the counter by 1 until the event count matches **GPTMTnMATCHR**. When the counts match, the GPTM asserts the CnMRIS bit in the **GPTMRIS** register (and the CnMMIS bit, if the interrupt is not masked).

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 245.

The counter is then reloaded using the value in **GPTMTnILR**, and stopped because the GPTM automatically clears the TnEN bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until TnEN is re-enabled by software.

Figure 11-2 on page 438 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted since the timer automatically clears the TnEN bit after the current count matches the value in the **GPTMTnMR** register.

**Figure 11-2. 16-Bit Input Edge-Count Mode Example**

### 11.3.3.3 16-Bit Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

The prescaler is not available in 16-Bit Input Edge-Time mode.

In Edge-Time mode, the timer is configured as a 16-bit free-running down-counter. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** register (or 0xFFFF at reset). In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the TnCMR bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the TnEVENT fields of the **GPTMCnTL** register.

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current Tn counter value is captured in the **GPTMTnR** register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit (and the CnEMIS bit, if the interrupt is not masked). The **GPTMTnV** is the free-running value of the timer and can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 245.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the 0x0000 state, it is reloaded with the value from the **GPTMnILR** register.

Figure 11-3 on page 439 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** register, and is held there until another rising edge is detected (at which point the new count value is loaded into **GPTMTnR**).

**Figure 11-3. 16-Bit Input Edge-Time Mode Example**

#### 11.3.3.4 16-Bit PWM Mode

**Note:** The prescaler is not available in 16-Bit PWM mode.

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a down-counter with a start value (and thus period) defined by **GPTMTnILR**. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.

When software writes the TnEN bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0000 state. On the next counter cycle, the counter reloads its start value from **GPTMTnILR** and continues counting until disabled by software clearing the TnEN bit in the **GPTMCTL** register. No interrupts or status bits are asserted in PWM mode.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** register (its start state), and is deasserted when the counter value equals the value in the **GPTM Timer n Match Register (GPTMnMATCHR)**. Software has the capability of inverting the output PWM signal by setting the TnPWML bit in the **GPTMCTL** register.

Figure 11-4 on page 440 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and TnPWML = 0 (duty cycle would be 33% for the TnPWML = 1 configuration). For this example, the start value is **GPTMnIRL**=0xC350 and the match value is **GPTMnMR**=0x411A.

Figure 11-4. 16-Bit PWM Mode Example

### 11.3.3.5 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the `TnWOT` bit in the **GPTMTnMR** register. When the `TnWOT` bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is in 32-bit mode (controlled by the `GPTMCFG` bit in the **GPTMCFG** register), it triggers Timer A in the next module. If Timer A is in 16-bit mode, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Care must be taken that the `TAWOT` bit is never set in GPTM0. Figure 11-5 on page 440 shows how the `GPTMCFG` bit affects the daisy chain. This function is valid for both one-shot and periodic modes.

Figure 11-5. Timer Daisy Chain

### 11.3.4 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller transfers 8 items, until all 256 items have been transferred.

No other special steps are needed to enable Timers for  $\mu$ DMA operation. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 241 for more details about programming the  $\mu$ DMA controller.

## 11.4 Initialization and Configuration

To use the general-purpose timers, the peripheral clock must be enabled by setting the **TIMER0**, **TIMER1**, **TIMER2**, and **TIMER3** bits in the **RCGC1** register (see page 179). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module (see page 191). To find out which GPIO port to enable, refer to Table 24-4 on page 1090. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 342 and Table 24-5 on page 1099).

This section shows module initialization and configuration examples for each of the supported timer modes.

### 11.4.1 32-Bit One-Shot/Periodic Timer Mode

The GPTM is configured for 32-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TAEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TAMR** field in the **GPTM Timer A Mode Register (GPTMTAMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TASNAPS**, **TAWOT**, **TAMTE**, and **TACDIR** bits in the **GPTMTAMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. Load the start value into the **GPTM Timer A Interval Load Register (GPTMTAILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TAEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the TAMIE bit in the **GPTMTAMR** register is set, the RTCRIS bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

### 11.4.2 32-Bit Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the TAEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
3. Write the match value to the **GPTM Timer A Match Register (GPTMTAMATCHR)**.
4. Set/clear the RTCEN bit in the **GPTM Control Register (GPTMCTL)** as needed.
5. If interrupts are required, set the RTCIM bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTAMATCHR** register, the counter is re-loaded with 0x0000.0000 and begins counting. If an interrupt is enabled, it does not have to be cleared.

### 11.4.3 16-Bit One-Shot/Periodic Timer Mode

A timer is configured for 16-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0004.
3. Set the TnMR field in the **GPTM Timer Mode (GPTMTnMR)** register:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the TnSNAPS, TnWOT, TnMTE and TnCDIR bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the start value into the **GPTM Timer Interval Load Register (GPTMTnILR)**.
7. If interrupts are required, set the appropriate bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
8. Set the TnEN bit in the **GPTM Control Register (GPTMCTL)** to enable the timer and start counting.

9. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the TnMIE bit in the **GPTMTnMR** register is set, the RTCRIS bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

#### 11.4.4 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x0 and the TnMR field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. Load the event count into the **GPTM Timer n Match (GPTMTnMATCHR)** register.
8. If interrupts are required, set the CnMIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
9. Set the TnEN bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
10. Poll the CnMRIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnMCINT bit of the **GPTM Interrupt Clear (GPTMICR)** register.

In Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the TnEN bit is cleared and repeat step 4 on page 443 through step 9 on page 443.

#### 11.4.5 16-Bit Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x1 and the TnMR field to 0x3.
4. Configure the type of event that the timer captures by writing the TnEVENT field of the **GPTM Control (GPTMCTL)** register.

5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the CnEIM bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the CnERIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnECINT bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

#### 11.4.6 16-Bit PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the TnEVENT field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
6. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
7. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

### 11.5 Register Map

Table 11-5 on page 445 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- Timer0: 0x4003.0000
- Timer1: 0x4003.1000
- Timer2: 0x4003.2000
- Timer3: 0x4003.3000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 179).

**Table 11-5. Timers Register Map**

| Offset | Name         | Type | Reset       | Description                  | See page |
|--------|--------------|------|-------------|------------------------------|----------|
| 0x000  | GPTMCFG      | R/W  | 0x0000.0000 | GPTM Configuration           | 446      |
| 0x004  | GPTMTAMR     | R/W  | 0x0000.0000 | GPTM Timer A Mode            | 447      |
| 0x008  | GPTMTBMR     | R/W  | 0x0000.0000 | GPTM Timer B Mode            | 449      |
| 0x00C  | GPTMCTL      | R/W  | 0x0000.0000 | GPTM Control                 | 451      |
| 0x018  | GPTMIMR      | R/W  | 0x0000.0000 | GPTM Interrupt Mask          | 454      |
| 0x01C  | GPTMRIS      | RO   | 0x0000.0000 | GPTM Raw Interrupt Status    | 456      |
| 0x020  | GPTMMIS      | RO   | 0x0000.0000 | GPTM Masked Interrupt Status | 459      |
| 0x024  | GPTMICR      | W1C  | 0x0000.0000 | GPTM Interrupt Clear         | 462      |
| 0x028  | GPTMTAILR    | R/W  | 0xFFFF.FFFF | GPTM Timer A Interval Load   | 464      |
| 0x02C  | GPTMTBILR    | R/W  | 0x0000.FFFF | GPTM Timer B Interval Load   | 465      |
| 0x030  | GPTMTAMATCHR | R/W  | 0xFFFF.FFFF | GPTM Timer A Match           | 466      |
| 0x034  | GPTMTBMATCHR | R/W  | 0x0000.FFFF | GPTM Timer B Match           | 467      |
| 0x038  | GPTMTAPR     | R/W  | 0x0000.0000 | GPTM Timer A Prescale        | 468      |
| 0x03C  | GPTMTBPR     | R/W  | 0x0000.0000 | GPTM Timer B Prescale        | 469      |
| 0x040  | GPTMTAPMR    | R/W  | 0x0000.0000 | GPTM TimerA Prescale Match   | 470      |
| 0x044  | GPTMTBPMR    | R/W  | 0x0000.0000 | GPTM TimerB Prescale Match   | 471      |
| 0x048  | GPTMTAR      | RO   | 0xFFFF.FFFF | GPTM Timer A                 | 472      |
| 0x04C  | GPTMTBR      | RO   | 0x0000.FFFF | GPTM Timer B                 | 473      |
| 0x050  | GPTMTAV      | RW   | 0xFFFF.FFFF | GPTM Timer A Value           | 475      |
| 0x054  | GPTMTBV      | RW   | 0x0000.FFFF | GPTM Timer B Value           | 476      |

## 11.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

GPTM Configuration (GPTMCFG)

Timer0 base: 0x4003.0000  
Timer1 base: 0x4003.1000  
Timer2 base: 0x4003.2000  
Timer3 base: 0x4003.3000  
Offset 0x000  
Type R/W, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset      | Description                                                                                                                                                                                   |
|-----------|----------|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:3      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 2:0       | GPTMCFG  | R/W  | 0x0        | GPTM Configuration                                                                                                                                                                            |

The GPTMCFG values are defined as follows:

| Value | Description                                                                                                 |

## Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the TAAMS bit, clear the TACMR bit, and configure the TAMR field to 0x2.

In 16-bit timer configuration, TAMR controls the 16-bit timer modes for Timer A. In 32-bit timer configuration, this register controls the mode, and the contents of **GPTMTBMR** are ignored.

### GPTM Timer A Mode (GPTMTAMR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

### Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the TBAMS bit, clear the TBCMR bit, and configure the TBMR field to 0x2.

In 16-bit timer configuration, these bits control the 16-bit timer modes for Timer B. In 32-bit timer configuration, this register's contents are ignored, and **GPTMTAMR** is used.

#### GPTM Timer B Mode (GPTMTBMR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

|           |          |      | 1         | If Timer B is enabled (TBEN is set in the <b>GPTMCTL</b> register), Timer B does not begin counting until it receives an it receives a trigger from the timer in the previous position in the daisy chain. See Figure 11-5 on page 440. This function is valid for both one-shot and periodic modes. |

## Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

### GPTM Control (GPTMCTL)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x00C  
 Type R/W, reset 0x0000.0000

**Register 5: GPTM Interrupt Mask (GPTMIMR), offset 0x018**

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

**GPTM Interrupt Mask (GPTMIMR)**

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x018  
 Type R/W, reset 0x0000.0000
