

Section 10. I/O Ports

HIGHLIGHTS

This section of the manual contains the following topics:

10.1	Introduction	10-2
10.2	I/O PORTx Control Registers.....	10-3
10.3	Peripheral Multiplexing.....	10-5
10.4	Change Notification (CN) Pins	10-7
10.5	CN Operation in Sleep and Idle Modes	10-8
10.6	Registers.....	10-9
10.7	Related Application Notes.....	10-11
10.8	Revision History	10-12

Note: This family reference manual section is meant to serve as a complement to device data sheets. Depending on the device variant, this manual section may not apply to all dsPIC33F/PIC24H devices.

Please consult the note at the beginning of the “I/O Ports” chapter in the current device data sheet to check whether this document supports the device you are using.

Device data sheets and family reference manual sections are available for download from the Microchip Worldwide Web site at: <http://www.microchip.com>

10.1 INTRODUCTION

This section provides information on the I/O ports for the devices of dsPIC33F/PIC24H family. All the device pins (except VDD, VSS, MCLR, and OSC1/CLKI) are shared between the peripherals and the general purpose I/O ports.

The general purpose I/O ports allow the dsPIC33F/PIC24H to monitor and control other devices. Most I/O pins are multiplexed with alternate function(s). The multiplexing will depend on the peripheral features on the device variant. In general, when a peripheral is functioning, that pin may not be used as a general purpose I/O pin.

Figure 10-1 shows a block diagram of a typical I/O port. This block diagram does not take into account peripheral functions that may be multiplexed onto the I/O pin.

Figure 10-1: Dedicated Port Structure Block Diagram

10.2 I/O PORTx CONTROL REGISTERS

All I/O ports have four registers directly associated with the operation of the port, where 'x' is a letter that denotes the particular I/O port:

- TRISx: Data Direction registers
- PORTx: I/O Port registers
- LATx: I/O Latch registers
- ODCx: Open-Drain Control registers

Each I/O pin on the device has an associated bit in the TRISx, PORTx, and LATx registers.

Note: The total number of ports and available I/O pins will depend on the particular device. In a given device, all of the bits in a port control register may not be implemented. Refer to the “I/O Ports” chapter in the specific device data sheet for availability.

10.2.1 TRIS Registers

The TRISx register control bits determine whether each pin associated with the I/O port is an input or an output. If the TRISx bit for an I/O pin is a '1', then the pin is an input. If the TRISx bit for an I/O pin is a '0', then the pin is configured for an output. An easy way to remember this is that a '1' looks like an I (input) and a '0' looks like an O (output). All port pins are defined as inputs after a Reset.

10.2.2 PORT Registers

Data on an I/O pin is accessed via a PORTx register. A read of the PORTx register reads the value of the I/O pin, while a write to the PORTx register writes the value to the port data latch.

Many instructions such as `BSET` and `BCLR` instructions, are read-modify-write operations. Therefore, a write to a port implies that the port pins are read, this value is modified, and is written to the port data latch. Care should be taken when read-modify-write commands are used on the PORTx registers and when I/O pins associated with the port are configured as inputs. If an I/O pin configured as an input is changed to an output at some later time, an unexpected value may be output on the I/O pin. This effect occurs because the read-modify-write instruction reads the instantaneous value on the input pin and loads that value into the port data latch.

In addition, if read-modify-write instructions are used on the PORTx registers while I/O pins are configured as output, unintended I/O behavior may occur based on the device speed and I/O capacitive loading. [Figure 10-2](#) illustrates unintended behavior that occurs when the user application attempts to set I/O bits 0 and 1 on Port A with two consecutive read-modify-write instructions in the PORTA register. At high CPU speeds and high capacitive loading on the I/O pins, the unintended result of the example code is that only I/O bit 1 is set high.

Figure 10-2: Example of Unintended I/O Behavior

When the first `BSET` instruction is executed, it writes a '1' to bit 0 in the PORTA register, which causes the voltage level to start rising to logic level 1 on pin 0 (see Step 1 in Figure 10-2). However, if the second `BSET` instruction is executed before the voltage level on pin 0 has reached the threshold for logic 1 (Step 3 in Figure 10-2), the second `BSET` (read-modify-write) instruction reads '0' for bit 0, which it writes back into the PORTA register (Step 2 in Figure 10-2). In other words, instead of reading a value of 0x0001 from the PORTA register, it reads a value of 0x0000, modifies it to 0x0002 (instead of the desired value of 0x0003), and writes that value back to the PORTA register. This causes the voltage on pin 0 to start falling to logic 0 and the voltage on pin 1 to start rising to logic 1 (Step 4 in Figure 10-2).

10.2.3 LAT Registers

The LATx register associated with an I/O pin eliminates the problems that can occur with read-modify-write instructions. A read of the LATx register returns the values held in the port output latches instead of the values on the I/O pins. A read-modify-write operation on the LATx register associated with an I/O port avoids the possibility of writing the input pin values into the port latches. A write to the LATx register has the same effect as a write to the PORTx register.

The following example uses the LATx register to set two I/O bits.

Example 10-1: Setting I/O Pins with LATx Register

```
BSET   LATA, #0           ;Set pin 0 on Port A to '1'
BSET   LATA, #1           ;Set pin 1 on Port A to '1'
```

The differences between the PORTx and LATx registers can be summarized as follows:

- A write to the PORTx register writes the data value to the port latch
- A write to the LATx register writes the data value to the port latch
- A read of the PORTx register reads the data value on the I/O pin
- A read of the LATx register reads the data value held in the port latch

Any bit along with its associated data and control registers that are not valid for a particular device will be disabled. That means the corresponding LATx and TRISx registers, and the port pin will read as zero.

10.2.4 Open-Drain Control Registers

In addition to the PORTx, LATx and TRISx registers for data control, each port pin can also be individually configured for either digital or open-drain output. This is controlled by the Open-Drain Control register and ODCx that is associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than VDD (e.g., 5V) on any desired digital-only pins by using external pull-up resistors. The open-drain I/O feature is not supported on pins which have analog functionality multiplexed on the pin. The maximum open-drain voltage allowed is the same as the maximum V_{IH} specification. The open-drain output feature is supported for both port pin and peripheral configurations.

10.3 PERIPHERAL MULTIPLEXING

When a peripheral is enabled, the associated pin output drivers are typically module controlled, while a few are user settable. The term 'user settable' means that the associated peripheral port pin output driver is user configurable via the associated TRISx SFR. The TRISx register must be set properly for the peripheral to function properly. For user settable peripheral pins, the actual port pin state can always be read via the PORTx SFR.

The I/O pin can be read through the input data path, but the output driver for the I/O port bit is generally disabled.

An I/O port that shares a pin with another peripheral is always subservient to the peripheral. The peripheral's output buffer data and control signals are provided to a pair of multiplexers. The multiplexers select whether the peripheral or the associated port has ownership of the output data and control signals of the I/O pin. Figure 10-3 shows how ports are shared with other peripherals and the associated I/O pin to which they are connected.

Note: Some ports are shared with ADC module pins. The corresponding bits in the AD1PCFG and AD2PCFG registers, if present, must be set to '1' for I/O port functionality, even if the ADC module is turned off.

Figure 10-3: Shared Port Structure Block Diagram

10.3.1 I/O Multiplexing with Multiple Peripherals

For some dsPIC33F/PIC24H devices, especially those with a small number of I/O pins, multiple peripheral functions may be multiplexed on each I/O pin. Figure 10-3 shows an example of two peripherals multiplexed to the same I/O pin.

The name of the I/O pin defines the priority of each function associated with the pin. The conceptual I/O pin shown in Figure 10-3 has two multiplexed peripherals, Peripheral A and Peripheral B and is named PERA/PERB/PIO.

The I/O pin name is chosen so that the user application can easily tell the priority of the functions assigned to the pin. For the example shown in Figure 10-3, Peripheral A has the highest priority for control of the pin. If Peripheral A and Peripheral B are enabled at the same time, Peripheral A will take control of the I/O pins.

10.3.1.1 SOFTWARE INPUT PIN CONTROL

Some of the functions assigned to an I/O pin may be input functions that do not take control of the pin output driver. An example of one such peripheral is the Input Capture module. If the I/O pin associated with the Input Capture is configured as an output using the appropriate TRIS control bit, the user can manually affect the state of the Input Capture pin through its corresponding PORT register. This behavior can be useful in some situations, especially for testing purposes when no external signal is connected to the input pin.

Referring to [Figure 10-3](#), the organization of the peripheral multiplexers will determine whether the peripheral input pin can be manipulated in software using the PORTx register. The conceptual peripherals shown in this figure disconnect the Port data from the I/O pin when the peripheral function is enabled.

In general, the following peripherals allow their input pins to be controlled manually through the PORTx registers:

- External Interrupt pins
- Timer Clock Input pins
- Input Capture pins
- PWM Fault pins
- Most serial communication peripherals, when enabled take full control of the I/O pin so that the input pins associated with the peripheral are not affected through the corresponding PORT registers. These peripherals include the following:
 - SPI
 - I²C™
 - UART
 - ECAN™

Note: Some peripherals may not be present on all devices. Refer to the specific device data sheet for further information.

10.3.1.2 PIN CONTROL SUMMARY

When a peripheral is enabled, the associated pin output drivers are typically module controlled, while a few are user-settable. The term 'module control' means that the associated port pin output driver is disabled and the pin can only be controlled and accessed by the peripheral.

An Input Capture peripheral provides a good example of a user settable peripheral. The user application must write the associated TRISx register to configure the Input Capture pin as an input. Since the I/O pin circuitry is still active when the Input Capture is enabled, the following method can be used to manually produce capture events using software: The Input Capture pin is configured as an output using the associated TRISx register. Then, the software can write values to the corresponding LATx register drive to internally control the Input Capture pin and force capture events.

As another example, an INTx pin can be configured as an output and then by writing to the associated LATx bit, an INTx interrupt if enabled, can be generated.

The UART module is an example of a Module Control peripheral. When the UART is enabled, the PORTx and TRISx registers have no effect and cannot be used to write the RX and TX pins. Most communication peripheral functions available on the dsPIC33F/PIC24H are Module Control peripherals.

For example, the SPI module can be configured for Master mode in which only the SDOx pin is required. In this scenario, the SDIx pin can be configured as a general purpose output pin by clearing (setting to a logic '0') the associated TRISx bit. For more information on how pins can be configured for a module, refer to the specific module.

10.4 CHANGE NOTIFICATION (CN) PINS

The Change Notification (CN) pins provide the dsPIC33F/PIC24H family of devices the ability to generate interrupt requests to the processor in response to a change of state on selected input pins. Up to 24 input pins may be selected (enabled) for generating CN interrupts. The total number of available CN inputs is dependent on the selected dsPIC33F/PIC24H device. Refer to the device data sheet for further details.

Figure 10-4 shows the basic function of the CN hardware.

Figure 10-4: Input Change Notification Block Diagram

10.4.1 CN Control Registers

There are four control registers associated with the CN module. The CNEN1 and CNEN2 registers contain the CNxIE control bits, where 'x' denotes the number of the CN input pin. The CNxIE bit must be set for a CNx input pin to interrupt the CPU.

The CNPU1 and CNPU2 registers contain the CNxPUE control bits. Each CNx pin has a weak pull-up device connected to the pin that can be enabled or disabled using the CNxPUE control bits. The weak pull-up devices act as a current source that is connected to the pin and eliminates the need for external resistors when push button or keypad devices are connected. Refer to the “**Electrical Specifications**” chapter in the specific device data sheet for CN pull-up device current specifications.

10.4.2 CN Configuration and Operation

The CNx pins are configured as follows:

1. Ensure that the CNx pin is configured as a digital input by setting the associated bit in the TRISx register.
2. Enable interrupts for the selected CNx pins by setting the appropriate bits in the CNEN1 and CNEN2 registers.
3. Turn on the weak pull-up devices (if desired) for the selected CNx pins by setting the appropriate bits in the CNPU1 and CNPU2 registers.
4. Clear the CNIF interrupt flag in the IFSx register.
5. Select the desired interrupt priority for CNx interrupts using the CNIP<2:0> control bits in the IPCx register.
6. Enable CN interrupts using the CNIE control bit in the IECx register.

The CNx pins have a minimum input pulse width specification. Refer to the “**Electrical Specifications**” chapter in the specific device data sheet for further details. [Example 10-2](#) provides code for configuring and using CN interrupts.

Example 10-2: Configuring and Using CN Interrupts

```
void configure_CN(void)
{
    CNEN1bits.CN3IE = 1;           // Enable CN3 pin for interrupt detection
    IEC1bits.CNIE = 1;            // Enable CN interrupts
    IFS1bits.CNIF = 0;            // Reset CN interrupt
}

void __attribute__((__interrupt__)) _CNInterrupt(void)
{
    // Insert ISR code here

    IFS1bits.CNIF = 0;           // Clear CN interrupt
}
```

10.5 CN OPERATION IN SLEEP AND IDLE MODES

The CN module continues to operate during Sleep or Idle mode. If one of the enabled CNx pins changes states, the CNIF status bit in the IFSx register will be set. If the CNIE bit is set in the IECx register, the device will wake from Sleep or Idle mode and resume operation.

If the assigned priority level of the CN interrupt is equal to or less than the current CPU priority level, device execution will continue from the instruction immediately following the `SLEEP` or `IDLE` instruction.

If the assigned priority level of the CN interrupt is greater than the current CPU priority level, device execution will continue from the CN interrupt vector address.

10.6 REGISTERS

10.6.1 Change Notification Registers

The following registers are used to enable and disable the corresponding CN interrupts and pull-up resistors.

- [CNEN1: Input Change Notification Interrupt Enable Register 1](#)
- [CNEN2: Input Change Notification Interrupt Enable Register 2](#)
- [CNPU1: Input Change Notification Pull-up Enable Register 1](#)
- [CNPU2: Input Change Notification Pull-up Enable Register 2](#)

10.7 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the dsPIC33F/PIC24H Product Family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the I/O Ports module include the following:

Title	Application Note #
Implementing Wake-up on Key Stroke	AN552

Note: Please visit the Microchip web site (www.microchip.com) for additional Application Notes and code examples for the dsPIC33F/PIC24H Family of devices.

10.8 REVISION HISTORY

Revision A (February 2007)

This is the initial released version of this document.

Revision B (February 2007)

Minor edits throughout document.

Revision C (September 2008)

This revision incorporates the following updates:

- Registers:
 - The bit description for bit 15-0 has been corrected (see [Register 10-3](#))
 - The bit description for bit 7-0 has been corrected (see [Register 10-4](#))
- Additional minor corrections such as language and formatting updates were incorporated throughout the document

Revision D (January 2012)

This revision includes the following updates:

- Removed the second paragraph in [10.4.2 “CN Configuration and Operation”](#)
- All references to dsPIC33F have been changed to dsPIC33F/PIC24H
- The Preliminary document status has been removed
- Minor updates to text and formatting have been incorporated throughout the document

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.
