

MIC4811 Evaluation Board

High Current 6 Channel Linear WLED Driver with DAM™ and Ultra Fast PWM™ Control

General Description

The MIC4811 is a high efficiency linear White LED (WLED) driver; it is designed to drive up to six high current WLEDs while maintaining constant current in each channel. The MIC4811 features Dynamic Average Matching™ (DAM™) which is specifically designed to provide optimum matching across all WLEDs. These high accuracy ($\pm 1\%$ typical) current regulated WLED channels ensure uniform display illumination under all conditions. A typical dropout of 100mV at 50mA is expected.

The MIC4811 is available in a 10-pin MSOP package with a junction temperature range of -40°C to $+125^{\circ}\text{C}$.

Datasheets and support documentation can be found on Micrel's web site at: www.micrel.com

Requirements

The MIC4811 evaluation board requires a power supply that is capable of delivering at least 1A while providing an input voltage between 3.0V and 5.5V.

Precautions

The MIC4811 evaluation board is designed for an input voltage no greater than 6V. This evaluation board does not have reverse polarity protection; hence, applying a negative voltage to the V_{IN} terminal may damage the device.

Getting Started

- 1. Connect an external supply to V_{IN} .** Apply the desired input voltage across V_{IN} and ground terminals, J1 and J2, respectively, paying careful attention to polarity and supply voltage ($3.0\text{V} \leq V_{IN} \leq 5.5\text{V}$). An ammeter may be placed between the input supply and the V_{IN} terminal to the evaluation board. Ensure that the supply voltage is monitored at the V_{IN} terminal. The ammeter and/or power lead resistance can reduce the voltage supplied to the input.

2. Enable/Disable the MIC4811

To enable the device, apply a DC voltage of 1.2V or greater to the EN pin (J3). This allows for full brightness of the WLEDs (100% duty cycle). The EN pin can also be used for dimming by connecting a PWM signal and varying its duty cycle (please refer to the Ultra Fast PWM™ Dimming Interface Section in datasheet). Pulling EN low for more than 20ms forces the MIC4811 into a low I_Q sleep mode. Do not leave the EN pin floating as this may cause an indeterminate output state. A pull down resistor of 200k Ω is placed from EN to GND to ensure that the WLEDs are OFF when an enable signal is not applied.

3. Setting LED current with R_{SET} resistor.

The average LED current may be calculated using the equation below:

$$R_{SET} (k\Omega) = \frac{820 \cdot D}{I_{LED} (mA)} + 0.139$$

$$I_{LED} (mA) = \frac{820 \cdot D}{(R_{SET} (k\Omega) - 0.139)}$$

D is the duty cycle of the LED current during PWM dimming; $D=1$ when device is fully ON. The stock evaluation board uses an R_{SET} value of 16.5k Ω which corresponds to I_{LED} of 50mA.

4. Measuring WLED current.

To measure WLED current, simply insert an ammeter in series with the WLED(s). Keep in mind that a series ammeter will add a small voltage drop, so the voltage at the WLED terminal(s), D1-D6, should be used when making dropout measurements with a series ammeter.
